TABLE 2.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals—Continued			
Zinc:			
Scrap	709	1,012	Italy 984; France 28.
Slab	54	91	Mainly to Italy.
Semimanufactures	52	76	West Germany 36; Austria 14; Italy 10.
Other ore and concentrate	20	673	Mainly to West Germany.
Other base metals	[3] 24	15	Netherlands 6; West Germany 4.
Nonmetals:			
Abrasives, natural	2	26	Netherlands 10.
Asbestos	34	21	West Germany 9; France 4.
Cement	24,510	20,630	West Germany 18,100; France 2,440.
Chalk	22	18	Mainly to West Germany.
Clays	11,021	12,667	West Germany 11,073; Austria 1,537.
Diamond, industrial thousand carats and other.	13,530	15,130	West Germany 4,070; India 3,295; United Kingdom 2,280.
Diatomite and other siliceous earths	79	152	West Germany 73; Belguim-Luxembourg 33.
Dolomite	155	160	Denmark 75; Netherlands 75.
Feldspar, leucite, etc.	7	58	Austria 20; West Germany 12.
Gypsum	166	73	Italy 38; West Germany 16.
Lime	1,212	3,327	West Germany 1,343; Austria 980; France 949.
Limestone, industrial	3,115	2,291	Mainly to West Germany.
Magnesite	6	24	West Germany 5.
Mica	25	20	France 6; Italy 5; West Germany 5.
Quartz and quartzite	2,427	6,615	Italy 4,121; West Germany 1,132; Belgium-Luxembourg 530.
Sand, gravel, crushed thousand tons rock.	75	63	West Germany 30; Austria 27.
Shale	647	451	West Germany 398; France 52.
Stone, other	22,631	22,590	Mainly to West Germany.
Talc and steatite	123	1,108	Mainly to Italy.
Other	22	20	(4).
Mineral fuels:			
Coal:			
Anthracite and bituminous	3	1,774	France 1,000; Netherlands 757.
Lignite, including briquets	2,538	167	All to West Germany.
Peat	222	202	(4).
Coke	314	394	All to Italy.
Tar, coal and mineral	1	46	West Germany 24; France 11.
Petroleum refinery products:			
Gasoline [5]	47	5	(4).
Kerosine	8	7	Mainly to West Germany.
Distillate fuel oil	17	12	Italy 9; France 3.
Residual fuel oil	1	37	Mainly to Italy.
Lubricants	1,094	1,242	Italy 480; Burma 417; India 47.
Liquefied petroleum gases	80	1	(4).
Asphalt and bitumens	2,441	2,306	Asphalt: West Germany 119. Bitumens mainly to United Kingdom.
Petroleum coke	3,773	8,873	France 6,474; West Germany 1,766; Italy 633.
Other	137	64	(4).
Carbon black	511	628	Italy 438; West Germany 102.

[1] Includes other metals not specified.
[2] Includes sponge iron, shot, grit, and pellets.
[3] Includes antimony.
[4] No principal destination; distributed in small quantities to a number of countries.
[5] Includes white spirit.

Asphalt and bitumens	5,280	5,612	West Germany 1,499; United States 1,074; Italy 960.
Petroleum coke	27,486	36,531	West Germany 24,846; United States 10,729.
Other thousand tons	138	156	West German 41; France 31; Netherlands 30.
Carbon black	5,445	5,758	West Germany 1,300; United States 1,265; Netherlands 962.

[1] Includes other metals not specified.
[2] Includes sponge iron, shot, grit, and pellets.
[3] Includes antimony.
[4] Less than 0.5 ton.
[5] Includes white spirit.

COMMODITY REVIEW

METALS

Aluminum.—Production of aluminum has increased steadily with growing ingot capacity. The new plant of Alusuisse (Schweizerische Aluminum, G. m.b.H., formerly Aluminum Industrie, A.G.) at Steg (Canton Valais), which went into operation in 1962, raised domestic primary ingot capacity to 61,500 metric tons, distributed as follows: Alusuisse—35,000 tons ingot and 3,000 tons superpurity aluminum at Chippis (Canton Valais) and 18,000 tons ingot at Steg (Canton Valais); and Usine d'Aluminium Martigny—5,500 tons ingot at Martigny-Ville (Canton Valais). In addition, Metallwerke Refonda, Wiederkehr at Niederglatt (Canton Zurich) has annual capacity for 7,000 tons of secondary aluminum ingot. Twelve rolling and/or extrusion mills also operated in 1963. One was owned by Alusuisse, and several others were affiliated with Alusuisse.

Aluminum production has been based largely on alumina imported from Alusuisse operations in foreign countries. Bauxite and alumina came from Alusuisse's subsidiaries in France (S.A. des Bauxites de France), Greece, and West Africa. Through an agreement with the Government of Sierra Leone in 1962, Alusuisse established a subsidiary, Sierra Leone Ore and Metal Co., to mine bauxite in the southwest province of Sierra Leone. During 1962 Alusuisse also planned for an alumina plant, annual capacity 200,000 metric tons, near Rotterdam in the Netherlands at a reported cost of 200 million guilders. In 1963 the company participated in the financing of a new aluminum reduction plant, capacity 30,000 metric tons, in the Netherlands, with initial production anticipated for 1966. The Netherlands gasfields were to provide fuel for electric power requirements.

TABLE 4.—Aluminum semifabrication plants, 1963

Company	Plant location		Products, remarks
	City or town	Canton	
Aluminium Laufen, A.G.	Laufen	Bern	Sheet, strip, rods, extruded products.
Aluminium, A. G. Menziken	Menziken	Aargau	Sheet, strip, extruded products. Affiliated with Alusuisse.
Aluminium, A. G. Rorschach	Rorschach	St. Gallen	Sheet, foil. Annual capacity: 15,000 tons. Affiliated with Aluminum Co. of Canada (Alcan).
Schweizerische Aluminium, G.m.b.H. (Alusuisse).	Sierre	Valais	Sheet, strip, extruded products, rods, wire, tubes. Annual capacity: 45,000 tons.
Aluminium Press und Walzwerk Munchenstein, A.G.	Munchenstein	Baselland	Sheet, extruded products.
Laminoirs Ed. Mathey Fils S.A.	Neuveville	Bern	Sheet, strip.
Robert Victor Neher, A.G.	Kreuzlingen	Thurgau	Foil, thin sheet. Subsidiary of Alusuisse.
Nyffeler Corti et Cie	Kirchberg	Bern	Foil.
Presta, A.G.	Kesswill	Thurgau	Tubes.
S. A. des Cableries et Tréfileries de Cossonay.	Cossonay	Vaud	Wire. Affiliated with Alusuisse.
Schupbach et Cie	Burgdorf	Bern	Foil.
Schweizerische Metallwerke Selve et Cie.	Thun	do	Sheet, strip, rods, wire.

Alcoa (Aluminum Co. of America) established Alcoa International, S.A. in Lausanne in 1962. This company will direct Alcoa's worldwide operations outside the United States.

Copper.—Switzerland's metallurgical production of copper has been limited to small quantities of secondary copper from Compagnie des Produits Électrochimiques et Électrométallurgiques at Bex (Canton Vaud) and Refonda at Niederglatt (Canton Zurich). Copper requirements during 1963 continued to be supplied largely by imported refined copper and semimanufactured products.

Iron and Steel.—Switzerland's small production of iron ore, pig iron, and crude steel remained relatively unchanged during 1963. Iron ore and pig iron output were reduced slightly, while output of ingots and other primary forms increased 1 to 2 percent. About half of the crude steel supply and a greater proportion of the semimanufactured steel supply continued to be provided by imports.

During 1963 four companies produced iron and steel: Ludwig von Roll'schen Eisenwerke, A.G. at Gerlafingen (Canton Solothurn) and Choindez (Canton Bern); Von Moos Eisenwerke, A.G. at Emmenbrücke (Canton Lucerne); La Fonte Électrique, S.A., at Bex (Canton Vaud); and Valfonte, S.A. Produits Électrométallurgiques at Martigny-Ville (Canton Valais). Products were mainly electric furnace pig iron, crude steel, and ferrosilicon. Mill products were made by Von Roll'schen and Von Moos. Steelmaking capacity has been entirely electric, based on domestic and imported scrap and pig iron and a small proportion of domestic ore. Electric furnace pig iron capacity has not been expanded in recent years and remained an estimated 60,000 to 70,000 metric tons per year. Crude steel capacity is not known but during 1963 was probably in excess of 300,000 metric tons per year. Total electric pig iron and steel facilities have not been utilized fully

Digitized by Google

on an annual basis because of a shortage of electricity during the winter.

Magnesium.—Imports of scrap, ingot, and semimanufactured magnesium increased considerably during 1962. Small quantities of magnesium also were produced by two companies in Switzerland during 1963, but output is not known. S.A. pour la Fabrication du Magnesium produced ingots, powder, alloys, and semiproducts at Martigny-Ville (Canton Valais), and Metallwerke Refonda, Wiederkehr, made secondary ingots.

Nickel.—Trade in nickel scrap, matte, and metal remained relatively unchanged during 1962; similar conditions apparently existed during 1963. Secondary nickel for alloying was produced by Compagnie des Produits Électrochimiques et Électrométallurgiques at Bex (Canton Vaud).

Uranium.—Several significant discoveries of uranium deposits were made during 1962–63, and Swiss companies planned mergers for exploration and development purposes. Deposits have been located in the central Alps and also in the lower ranges. At Blapbach (Canton Bern), reserves estimated to contain 800 to 1,000 metric tons of uranium have been reported. Other important uranium occurrences were reported at Tiraun (Canton Graubünden), in the Emmental Valley (Canton Valais), and near Isérables and Naters (Canton Valais). Average grade of samples indicated high-grade ores, but mining appeared unlikely because foreign sources of refined uranium apparently could supply the limited domestic requirements.

Zinc.—Imports of crude and semifabricated zinc were reduced during 1962 and remained at approximately the same level during 1963. A large part of the zinc supply was received as slab zinc. Small quantities of secondary zinc were produced by Metallwerke Refonda, Wiederkehr.

NONMETALS

Cement and Lime.—Output of cement in 1963 was slightly lower than the peak reached in 1962, owing to decreased deliveries to hydroelectric power station construction projects, the principal consuming sector, and lower demand for other building and construction. Consumption of cement for hydroelectric power construction increased 17 percent in 1961, 12 percent in 1962, and less in 1963. Although cement production capacity has increased, during seasonal peak demands consumption exceeded output, necessitating imports of cement and clinker. During 1962–63 about 3 percent of total cement consumption was supplied by imports.

Hydraulic lime production, which also reached a peak in 1962 and declined during 1963, continued to provide adequate supplies for domestic consumption.

Gypsum.—Plants operated at full capacity during 1963, but actual output is not known. Demand for building and construction uses continued high. Moderate imports supplemented domestic production, so that available supplies were adequate. Larger storage silos, recently constructed, provided continuing supplies during seasonal peak consumption. Gips Union, A.G. is the leading producer and supplier of gypsum in Switzerland.

Digitized by Google

Salt.—Production of table and industrial salts expanded further and provided sufficient supply for domestic consumption, which reached 168,000 metric tons in 1962 and an estimated 170,000 tons in 1963. Production remained centered in the Rhine district, near Basel, and near Bex (Canton Vaud).

Sulfur and Pyrite.—Imports of sulfur have increased in recent years, a trend which probably continued during 1963. The United States continued to be the principal source of sulfur, but France's Lacq gasfield also became an important source. As foreign supply of native and/or elemental sulfur grew, imports of pyrite from Italy were correspondingly curtailed during 1962. Sulfur, S.A., is a recently formed subsidiary of Continental Ore Corp., New York, with offices at Lausanne.

MINERAL FUELS

Coal.—Imported anthracite, bituminous coal, and lignite continued to be the sole source of coal supply in Switzerland. There has been no domestic production since 1957. Deposits of poor quality exist in and near the Alps, where mining has been difficult and expensive. Small quantities of peat were produced, but the great bulk of the supply also has been imported.

Output of manufactured gas and gas-plant coke reached new highs in 1962. Consumption of coal in gas plants totaled nearly 680,000 metric tons in 1962, slightly more than in 1961.

Petroleum.—Switzerland's supply of refined petroleum products was provided almost entirely by imports during 1963. The country's first oil refinery, that of Raffinerie du Rhône at Collembey-Murraz (Canton Valais), went on stream in September 1963, but the quantity and types of refined petroleum products delivered in the country are not known.

Imports of most petroleum products increased during 1962. The rate of consumption continued to rise, with the trend toward greater use of liquid fuels rather than solid fuels for production of energy. Imported petroleum coke was used in the manufacture of carbon electrodes by Alusuisse at Chippis (Canton Valais), where about 18,000 metric tons was produced during 1963. CeCe Graphitwerk, A.G., Zurich, continued to manufacture graphite products at a rate of 5,000 metric tons per year.

Annual capacity of the Collembey refinery is 40,000 barrels per day. Crude oil was supplied by a branch at Ferrara Station, Italy, from the new pipeline between Genoa, Italy, and Ingolstadt, West Germany, construction of which continued in 1963. Oleduc, S.A. (Société de l'Oleduc de Rhône, S.A.), primarily a Swiss company, operated the Ferrara Station-Collembey line. The 415-mile line across Switzerland to West Germany will have a capacity of 230,000 barrels per day. The portion of this line in Switzerland was owned and operated by Oleodotto del Reno, S.A., a Swiss and Italian company.

Numerous oil concessions have been granted in the Molasse Basin, Jura Plain, and Alpine mountain areas in recent years. SEAG (Schweizerische Erdöl, A.G.), a joint stock company, held more than half of these concessions in 1962. During 1963 this company completed a deep borehole near Pfaffnau (Canton Lucerne) and planned

Digitized by Google

further deep drilling near the Boden See, where the South German Basin extends into northern Switzerland, and in Canton Zurich.

Other concession holders included LEAG (Luzernisches Erdöl, A.G.); Société des Hydrocarbures, S.A.; Société d'Intérêts Minières; Société d'Études et Récherches Minières et Petrolières; and others. SEAG, LEAG, and Hydrocarbures are Swiss-German and have a common operator, Gewerkschaft Elwerth, A.G., in Switzerland. Hydrocarbures discovered a noncommercial oil deposit at Essertines in 1963.

Shell Switzerland planned a new oil refinery, capacity 2 million tons per year, near Cornaux-Cressier (Canton Neuchâtel). Crude oil would be supplied by pipeline from Marseilles. A 4-million-ton refinery also was planned by eight companies jointly participating in Mittelland Raffinerie, A.G. at Mägenwil (Canton Aargau), at a reported cost of SwF300 million. Another refinery was planned by Rheintal, A.G., at Sennwald (Canton St. Gallen), with crude oil provided by the Genoa-Ingolstadt pipeline.

The Mineral Industry of the U.S.S.R.

By V. P. Sokoloff [1]

THE U.S.S.R., with a centrally planned economy, has been the world's second largest industrial power in terms of the size of its total industrial output and of the value of its gross national product (GNP) for many years. In 1963 the GNP apparently exceeded that of 1962, which was estimated at about US$256 billion.[2] As during 1959–62, approximately 8 percent of the Soviet GNP was provided by the country's mineral output.

All mineral reserves and industries of the Soviet Union are nationally owned and government operated. Production schedules are mutually coordinated and production targets predetermined, in principle, by the 1959–65 national plan for economic development. Through 1963 production targets for the country's mineral industries were met successfully despite some administrative discoordination, mismanagement of individual enterprises, occasional disruption of procurement and supplies, and crises in other sectors of the Soviet economy.

In contrast to the first 3 years of the plan when emphasis in the Soviet mineral economy was on exploration, 1962–63 were for development and increased production. In 1964–65, the last 2 years of the plan, development was to be essentially completed and greater production achieved. During these 2 years and on the basis of mineral reserves, known and proven, as of 1963, overall industrial output was to show a further 17.5-percent increase over the 1963 level; the chemical industry sector (including mineral fertilizers and petrochemicals) was to register an increase of 36 percent. As recently as 1962, the already substantial mineral reserves of the Soviet Union were significantly increased by the platiniferous copper-nickel high-grade ores at Talnakh in Noril'sk Territory, Siberia and the rich oilfields at Ust'-Balyk and elsewhere in Tyumen' Territory, Siberia.

The government is committed to complete industrialization of the country, and national planning is based on the inventory of the country's proved and available mineral reserves. Economically the country has been growing eastward while expanding politically towards the peripheries of its European center. The politically secure and relatively densely populated center has been extraordinarily poor in natural mineral reserves, including fertile soils. The problem of the increasing distances between the minerals-endowed peripheries and the consuming core of the country has been recognized and solutions sought since the 15th century. However, the unfavorable geographic distribution pattern of the minerals base continued to tax the already

Digitized by Google

heavily burdened railways of the country. By 1963 more than 60 percent of rail transport, in terms of ton-kilometers, was committed to the haulage of low-unit cost but nonetheless essential mineral commodities. In some distant parts of the country, such as Yakutia and in northeast Siberia, some segments of the mining industry depended heavily on air freight.

In 1962–63 the planned modification of the economic-geographical distribution patterns on the Soviet industries was continued along the following lines—

1. Alleviation of regional shortages of fuels and water required by mining-metallurgical industries, mainly in Ural, Kazakhstan, Central Asia.
2. A more economic utilization of the available transportation and distribution systems, and a significant expansion of the trunk pipeline systems for the distribution of crude oil, oil refinery products, and natural gas.
3. A more efficient use of the available production capacities in ferrous and nonferrous metallurgy.
4. A gradual migration of ferrous industry eastward including a further expansion of the "Third Metallurgical Base of the U.S.S.R." [3] (in the Kuznetsk Territory, Siberia) and the beginning of the exploitation of vanadium-bearing phosphoripherous ironstones (previously regarded as uneconomic) in the Kustanay area, Kazakhstan.
5. Increased production of phosphate fertilizers from low-grade but easily enriched concretionary ores of the Russian Platform (previously regarded as uneconomic on account of the relatively small ore reserves of individual mines and pits).
6. A further increase in the relative share of opencast mining in the production of ferrous and nonferrous ores, phosphate ores, and coal.
7. A continuing increase in the number of persons employed in the national economy (68.3 million in 1962 as against 65.9 million in 1961) and a concurrently comparable increase in the numbers of the engineering-technological personnel of the Soviet mining-metallurgical industries.

The total employment figure includes 2.29 million technologists and engineers, 1.57 million of which are employed in industries and 217,000 in construction and maintenance.

Approximately 80 percent of the industrial engineering-technological force of the country is employed in heavy industries, as follows:

[3] The other two are Krivoy Rog, Ukraine and Ural, Russia.

Industry	Persons (thousands)
Metallurgy, metal fabrication, and machine-building	729
Ferrous	92
Coal	79
Electric power	46
Petroleum	24
Other	279

The distribution of specialists with university degrees in the Soviet industries, as of December 1, 1962, was as follows, in thousand persons:

Industry	Total specialists	Including engineers	Including engineers specialized in—				
			Mining-geology	Energetics, communications, radio-technology	Metallurgy and machine-building	Chemistry	Other
Iron-steel	35.4	30.1	4.0	3.6	17.0	2.6	2.9
Coal	22.0	19.8	15.6	3.5	.1	.1	.5
Petroleum	9.6	8.1	3.6	.5	1.0	2.6	.5
Electrical energy production	16.8	14.8	.1	11.7	.9	.3	1.8
Fabrication of metals and machine-building	266.6	207.0	1.9	22.7	142.7	10.1	29.6
Construction materials	20.8	16.1	2.1	.9	2.2	3.8	7.1
Other	198.1	134.7	8.4	6.8	24.2	20.0	75.2
Total	569.3	430.6	35.7	49.7	188.1	39.5	117.6

Wholesale prices of mineral raw materials and fuels in the Soviet heavy industry, last established in 1955, were partially revised in 1961–62, concurrently with the revision of the freight rates [4] following the July 1960 Plenum resolution and 1961 CPSU (Communist Party of the Soviet Union) Program. These revisions were made with attention to changes in the production costs, wages, the profit markup, and other variables and were to be implemented in 1963.

The following comparison is reproduced from Bornstein's study [5] based on the Soviet publications:

Branch of industry	Percentage change in the average branch price level
Coal	+30
Nonferrous ores	+15
Ferrous industry	+8.5
Construction materials	+2
Oil and products	−7
Gas	−10
Machine-building	−10
Chemicals	−14 to −15
Electrical power	−15
Railway freight	−20

[5] Bornstein, Morris. The 1963 Soviet Industrial Price Revision. Center for Russian Studies, University of Michigan, Soviet Studies, Ann Arbor Mich., 1963, v. 15, No. 1, pp. 43–52.

Digitized by Google

The revision did not affect the agricultural procurement prices (machinery, fertilizers, diesel fuel for tractors) and left the wholesale prices for the output of heavy industry practically unchanged (on the whole, 3 percent below their former levels). Thus the new price structure reflects increasing costs of primary products in extractive sectors of the Soviet economy (coal, ores) and decreasing costs in its processing sectors. However, the Soviet international trade prices are not to be influenced by the wholesale price revision within the country. The same applies to the Soviet domestic retail prices, which is to be regulated by the turnover tax, as formerly.

On the whole, the new price structure may be seen as a reallocation of the economic effort, particularly in the instance of the country's nonferrous and ferrous industries and in the instance of fuels, as a flexible provision for the uses of alternatives to coal. The 20-percent reduction in railway freight rates needs to be taken in relation to the modification in the country's transport structures already discussed.

SOURCE MATERIAL

Basic information on fuels, iron and steel, cement, sulfuric acid, refractories, and a number of other miscellaneous items are obtained from the Narodnoye Khozyastvo (National Economy of the U.S.S.R.), published annually by the Central Statistical Bureau at the Council of Ministers, U.S.S.R.; the 1963 data are derived from the quarterly reports of the Central Statistical Bureau published in Izvestiya, a daily newspaper. Estimated metal production data, except iron and steel and gold, are based on the U.S. Bureau of Mines open file materials. These estimates are interpretative extrapolations from often doubtful premises and represent, at best, an order of magnitude. Data on the production and sales of gold are quoted mainly from Samuel Montague's annual bullion reviews (London) and the Union Corporation, Ltd., reports (South Africa). Data on international trade of the Soviet Union came from the Vneshnyaya Torgovlya SSSR (Foreign Trade of the U.S.S.R.), a statistical review published annually by the VNESHTORGIZDAT (Press for Foreign Trade), Moscow.

Information on significant developments in 1963 are based upon or quoted from Soviet newspapers and magazines, including the following:

Newspapers: Izvestiya, Pravda, Eknomicheskaya Gazeta, and Stroyitel naya Gazeta.

Magazines: Gornyy Zhurnal (Mining Journal), Tsvetnyye Metally (Nonferrous Metals), Voprosy Ekonomiki (Eco-

Digitized by Google

nomic Problems), Planovoye Khozyaystvo (Planned Economy), Sovetskaya Geologiya (Soviet Geology), Vneshnyaya Torgovlya (Foreign Trade), and Ugol' (Coal).

Background information on the Soviet mineral industry was derived from a number of Soviet books, monographs, and symposia.

PRODUCTION

In 1962–63, about two-thirds of the increased output of Soviet mining and metallurgical industries was attained by a more efficient use of already available capacities rather than by commissioning of new. Inadequacies in the domestic supply of copper metal, power cable, large-diameter steel pipe, and several nonmetallic minerals were compensated by imports of these commodities as in previous years.

TABLE 1.—Estimated [1] production of metals and minerals

(Metric tons except where otherwise stated)

Commodity	1959	1960	1961	1962	1963

TABLE 1.—Estimated [1] production of metals and minerals—Continued

(Metric tons except where otherwise specified)

Commodity	1959	1960	1961	1962	1963
Nonmetals—Continued					
Sulfur, total [11] thousand tons	2,150	2,400	2,600	2,700	2,850
Talc, soapstone and pyrophyllite [3]	200,000	205,000	210,000	205,000	215,000
Vermiculite	(5)	(5)	50,000	150,000	(5)
Mineral fuels:					
Coal:					
Brown [12] thousand tons	141,386	138,261	133,516	130,976	140,000
Hard: [13]					
Coking do	100,805	110,198	112,247	117,462	127,000
Anthracite [14] do	79,309	78,013	77,480	76,364	263,000
Undifferentiated [6] do	185,106	186,714	187,292	192,606	
Total do	365,220	374,925	377,019	386,432	390,000
Crude oil [15] do	129,557	147,859	166,068	186,244	206,000
Oil shale [16] do	13,682	14,147	15,174	16,370	18,308
Peat do	60,500	53,600	51,600	34,700	35,000
Natural gas [17] million cubic feet	1,388,304	1,754,040	2,201,182	2,743,953	3,414,780
Electric power billion kilowatt hours	[18] 265	292	328	369	412

[1] Estimated, except where noted.
[2] Total estimated at 10 to 13 million troy ounces annually, data are insufficient to estimate annual fluctuations because of variations in placer output, which apparently account for 55 to 60 percent of total output.
[3] Reported in Soviet sources.
[4] Include steel produced from scrap. Soviet sources in 1963 stated that about half of all U.S.S.R. pig iron and steel are produced from scrap. For 1960, ferrous scrap consumption was reported as 35 million tons, not including 170,000 tons exported.
[5] Data not available.
[6] By difference between reported total and listed detail.
[7] Excludes stock for export; such stocks are included under separate items under semimanufactures.
[8] Includes pipe from ingots and pipe produced from steel pipe stock (both listed above) and additional pipe produced from unspecified materials. Data is also presented in terms of length of pipe in million meters, as follows: 1959, 802; 1960, 883; 1961, 991; 1962, 1,126; 1963, 1,240 (tonnage not reported in 1963).
[9] Detail above do not add to total because some items are listed twice in detail. This total excludes all duplication.
[10] Excludes synthetic diamond, produced on an industrial scale since 1959.
[11] Includes sulfur content of pyrite.
[12] Heat value 3,500 to 7,400 kilocalories per kilogram; specific gravity 1.1 to 1.2; 67 to 68 percent carbon; 41 to 50 percent volatile substance; 10 to 25 percent water.
[13] Heat value up to 8,200 kilocalories per kilogram; 75 to 97 percent carbon; 2 to 45 percent volatile substance; 3 to 12 percent water.
[14] Heat value 8,000 to 8,200 kilocalories per kilogram; 92 to 97 percent carbon, specific gravity 1.4 to 1.8; less than 6 percent volatile substance.
[15] Reportedly 45 to 55 percent by weight consists of light products.
[16] Estonian and Leningrad shales only.
[17] Including gas produced from oil wells, of which 5.5 billion cubic meters was produced in 1959. Also includes gas manufactured from coal and shale.
[18] Includes 18 percent from hydroelectric plants and 82 percent from thermal plants.

TRADE

By 1961–62, the Soviet Union had become the world's largest exporter of manganese ore, the second largest of coal, the fourth largest of iron ore and chromium ore, the fifth largest of aluminum and rolled ferrous metals,[6] one of the three largest of precious metals, the seventh largest of crude petroleum and petroleum refinery products.

Generally, about 60 percent of the Soviet mineral trade, as a whole, remains within the SEV (Soviet Ekonomicheskoy Vzayimopomoshchi) zone, very much like mineral (and total) trade of the other SEV member countries. The SEV, established in 1949, comprises Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Rumania, and Mongolia, in addition to the U.S.S.R. This intramural character of the large share of the SEV trade makes it difficult to appraise

[6] Vneshnyaya Torgovlya SSSR (Foreign Trade), November 1963, pp. 8–17.

Digitized by Google

the influence of the Soviet Union's trade on world markets aside and apart from the collective influence of the SEV community.

Excluding proceeds from the Soviet sales of precious metals outside the SEV zone, the favorable balance of the total trade of the Soviet Union in 1961 and 1962 was 154 million rubles and 526 million rubles, respectively. The favorable balance of the Soviet mineral trade only, in the same years, was 1,054 and 1,346 million rubles, respectively.

TABLE 2.—Value of metal and mineral foreign trade distributed by geographical and political areas

Grand total	2,121	2,406	1,067	1,060

[1] One ruble = US$1.11 at the official rate of exchange.
[2] Includes Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, and Rumania in Europe, and Mongolia in Asia.
[3] Less than 500,000 rubles.
[4] Data not available.
[5] Calculated; difference between reported distribution and reported total.

The relative importance of the major mineral commodity groups within the favorable balance of the Soviet mineral trade may be illustrated by the following comparisons:

Commodity group	Percent of favorable balance	
	1961	1962
Crude petroleum and refinery products	52	50
Iron, manganese, chromium ores	19	18
Coal, coke, anthracite	17	18
Mineral fertilizers and nonmetals	8	8
Others	4	6

The ruble value of the Soviet net exports of crude petroleum and refinery products was about 571 million and 637 million rubles in 1961 and 1962, respectively (higher than the entire total all-trade favorable balance in both instances).

Digitized by Google

The Soviet Union, the world's second largest producer of crude petroleum and refinery products, was responsible only for 5 percent of the world's international trade in these commodities.[7] The Soviet net exports of petroleum crudes and products were small, by world standards, and smaller still, if the net exports to the SEV countries are excluded.[8]

Geographically, the Soviet crude oil and refinery products trade has been significantly oriented toward Europe. Moreover, this commodity group accounted for 65 percent of the Soviet mineral exports to Western Europe outside the SEV zone, both in 1961 and in 1962.

The relative dependence of various countries on crude oil and refinery product imports from the Soviet Union ranges widely as shown in the following tabulation.[9]

Country	Net imports of crude oil and refinery products in 1962	
	Thousand metric tons	Percent of net imports from the U.S.S.R.
Iceland	320	97
Finland	3,260	90
Greece	1,860	45
Austria	1,450	28
Italy	33,930	21
Sweden	14,480	18
West Germany	41,840	7
Norway	3,960	5
Belgium	8,690	4
Denmark	6,720	3
France	33,720	2
United Kingdom	58,180	.3
Ceylon	1,100	16
Japan	40,000	7
India	9,300	5
Africa, total	23,000	8

[7] Vneshnyaya Torgovlya (Foreign Trade), March 1964, p. 16.
[8] The Soviet exports of crudes and products cover 97 percent of the SEV zone's needs for crudes and 60 percent for refinery products.

TABLE 3.—Value of metal and mineral trade distributed by major commodity groups

(Million rubles)

Commodity group	Exports		Imports	
	1961	1962	1961	1962
Metals:				
Ore and concentrate	227	246	264	270
Iron, ferroalloys, steel and steel mill products	640	713	364	384
Other	194	205	197	188
Total	1,061	1,164	825	842
Nonmetals:				
Construction materials	11	13	23	22
Mineral fertilizers	72	149	1	----
Other	36	36	16	13
Total	119	198	40	35
Mineral fuels:				
Coal and coke	256	312	84	86
Petroleum:				
Crude	289	331	15	8
Refinery products	393	398	96	84
Natural gas and carbon black	3	3	7	5
Total	941	1,044	202	183
Grand total	2,121	2,406	1,067	1,060

Soviet trade statistics displayed the following consistent trends during 1958–62: (1) Decreasing imports of fuels and raw materials, including mineral raw materials; (2) increasing imports of rolled and semifabricated steel, mainly from Japan, Austria, West Germany, Italy, United Kingdom, Rumania, and Czechoslovakia; (3) heavy imports of large-diameter steel pipe, reaching a peak in 1962; (4) increasing trade in machinery, equipment, semifabricates, and finished products; (5) and increasing exports of all basic raw materials, with the exception of lead, zinc, tin and nonferrous alloys.

Carbon black	4,800	5,600	Czechoslovakia 1,800; Bulgaria 1,000. (Unspecified 2,800.)	691	850

[1] Reported as "metal"; defined as "copper base, zinc-free alloy"—bronze.
[2] Reported as "latten"; defined as copper-zinc alloys.
[3] Calculated, by difference between various reported totals and sum of listed detail under these totals.
[4] Value only reported.
[5] Not reported, and not reliably determinable.
[6] Total of listed detail only; no estimates included for unreported quantities.
[7] Total not reported; detail given are derived from listings of trade with individual countries and may represent only part of total.
[8] Partly reported as such and partly calculated, by difference between reported total and sum of listed detail.
[9] Firmly welded deformable plates of two metals such as copper-aluminum, nickel-steel, or lead-tin.
[10] Carbide base alloys of high-temperature metals.
[11] Reported total is 15,893 thousand tons, but detail by country adds to 15,911 thousand tons.
[12] Officially reported as "mazut"; a term applied to residual products of oil refining which are suited for cracking column feed for production of fuel oils, lubricants, and paraffins. Category presumably includes material which may be used directly as fuel oil.

COMMODITY REVIEW

METALS

Iron Ore.—By the beginning of 1963, the Soviet iron ore industry operated 62 subsurface mines and 64 open pits. Of these, 12 mines and 13 pits, with the combined total capacity of 70 million tons of mined ore, were commissioned in 1959–61. More than 10 percent of the 1962 total output of mined ore is credited to these newly commissioned enterprises.

In 1963, 66 percent of mined iron ore (and 43 percent of mined manganese ore) were produced from open pits.

The mean grade of iron ores mined in the Soviet Union declined from more than 45 percent iron in 1959 to about 43 percent iron in 1962; the regional mean grade of the ore, from 25 percent iron (Ural) to 51 percent iron (the Kursk Magnetic Anomaly) remained essentially the same during that period.

The share of total iron ore output supplied by subsurface mines declined from more than 46 percent in 1959 to 35 percent in 1962. According to the national plan, 70 percent of mined ore will be obtained from open pits by the end of 1965.

Production of commercial ore, including iron ore concentrates containing about 60 percent iron and subordinate quantities of 56 to 60 percent iron run-of-mine ores, increased from 94 million tons in 1959 to 128 million tons in 1962 and to 137 million tons in 1963.

Production costs of commercial ore, expressed in kopeks per ton-percent iron (1 kopek=US$0.011), varied from 10.0 (Transcaucasia) to 4.5 (The Kursk Magnetic Anomaly), compared with the national average of 5.8 in 1962.[10]

As of January 1, 1962, the proved reserve of economic iron ores was 46 billion tons compared with 43 billion tons at the end of 1959. The increase of 3 billion tons was obtained by upgrading the reliability rating of some of the known but insufficiently explored bodies of economic iron ores. However, the economic reserve of high-grade ores that require no enrichment (56 percent iron, on the average) declined

[10] Skobwikov, M. L. Gornyyi Zhurnal (Mining Journal), 1962, No. 8, pp. 3–6.

Digitized by Google

from 9.8 billion tons in 1960 to 9.0 billion tons in 1962, possibly as the result of a reappraisal of geographical and mining environments.

There was no reported change in the total reserve of economic iron ores, as of 1959: 93 billion tons averaging 39.8 percent iron. On the average, 74 percent of the total ore reserve is suited for open pit mining. Of the total open pit ore, the largest part consists of easily upgraded magnetite taconites and others, with a mean iron content of 34 percent; about one-third is hematite martites and other technologically difficult ores, and less than 4 percent are high-grade ores (56 percent iron) requiring no enrichment.

Of the subsurface reserve, a little more than 10 billion tons containing 45 percent iron, consists entirely of high-grade and of easily upgraded ores.

The U.S.S.R.'s total reserve of proved minable economic iron ore, 46 billion tons, is equivalent to 24 billion tons of commercial ore, calculated as 60 percent iron concentrate. The ultimate possible production peak is estimated at 479 million tons of commercial ore annually.

Geographical distribution of the iron ore reserve and of mining and milling productive capacities has been changing progressively since 1959.

TABLE 7.—Distribution of iron ore reserve and production of commercial ore by region or basin

(Percent)

Region or basin [1]	Mean grade of reserve (percent iron)	Share the U.S.S.R. total				
		Reserve	Production of commercial ore			
			1959	1960	1961	1962
Ural-Kazakhstan [2]	33	32	33	31	29	29
European Center (Kursk Magnetic Anomaly)	51	25	2	4	5	6

East-Siberia	39	9	1	2	2	2
Northwest (Kola-Karelia)	32	4	2	2	2	3
European South (Kerch)	37	3	4	4	4	3
West-Siberia	39	2	4	4	4	4
Transcaucasia (Dashkesan)	40	Small	1	1	1	1
Far East	39	1	Small	Small	Small	Small

[1] Districts within the region accounting for more than nine-tenths of the region's production are named in parentheses, except as noted.

[2] Including the ore base (the Kustanay District) and the output of the Sokolov-Sarbay Kombinat, Western Kazakhstan, and the ore base but not the output of the Karaganda District, Central Kazakhstan; the mining-milling developments in Karaganda began on an appreciable scale only in 1963–64. The Kachkanar pits, eventually the largest mines of the region, yielded their first ore only in 1962.

The continuing shift in the geography of mining and milling in 1963–64 may have already increased significantly the role of Ural and Western Kazakhstan in the Soviet iron ore industry.

It is possible that the planned increase in the production of commercial iron ore, from 137 million tons in 1963 to 142 million tons in 1964 and 154 million tons in 1965, may be accomplished primarily by increasing the output of the Ural-West Kazakhstan's mining and milling operations. The Kachkanar alone was expected to yield 3 million tons of commercial ore in 1963.

Iron and Steel.—In 1963 the iron and steel industry made a number of additions to and improvements in facilities. Newly commissioned capacities included two blast furnaces, six Martin (open-hearth) furnaces, and five electrical furnaces for steel.

The number of blast furnaces using natural gas was increased to 69 (out of the estimated total of 95). Combined output of pig iron from natural gas-fueled furnaces represented about 60 percent of the country's total output of pig iron. The number of blast furnaces operating at high-gas pressures up to 0.7 atmospheres and experimentally as high as 1.8 atmospheres over the charge at the end of 1963 was 91, corresponding to 88 percent of the country's total blast-furnace capacity. The number of Martin (open-hearth) furnaces using oxygen blast was increased to 83, compared with 80 in 1962; their combined total output of steel was 20 million tons (17.9 million tons in 1962). A high-capacity oxygen converter installation at the Nizhniy Tagil' Kombinat [11] produced its first steel. Three new plants for the production of large-diameter (1,020 millimeters) steel pipe, 5 oxygen installations, and 13 agglomeration systems went into operation.

In 1963, compared with production in 1962, the country produced 3.5 million tons more pig iron, 3.8 million tons more steel, 2.8 million tons more rolled ferrous metals, and 660,000 tons more steel pipe.

Additional planned capacities under 1964–65 targets were to include 4 blast furnaces, 9 open-hearth furnaces, 6 oxygen blast converters, 12 installations for continuous casting of steel, 12 steel-rolling installations, 6 steel pipe factories, 18 iron ore and manganese ore mining enterprises, 13 agglomeration belts, 2 agglomeration plants, and additional facilities for production of ferroalloys and of sulfuric acid.

However, the planned production increase in 1964–65 will be attained mainly by a better use of already available capacities. The indicated production targets are as follows:

Commodity	Target (million tons)	
	1964	1965
Pig iron:		
From oxygen furnaces using natural gas	6.0	10.0
Other	55.5	55.7
Total	61.5	65.7
Steel:		
Oxygen converter	4.2	5.1
Oxygen blast Martin furnace	29.5	35.8
Cast by continuous process	1.1	1.3
Iron ore concentrates containing 65 percent iron or more	14.5	26.7

The 1965 production goal for steel has been given as 84 million tons,[12] compared with a 97 million ton goal set previously.

[11] Construction was begun in 1962. The Kombinat is based on vanadiferous iron ores of Kachkanar and is scheduled to yield nine-tenths of the Ural's regional output of iron by 1965. The estimated capacity output of the Kachkanar pits and mines may be about 40 million tons of low grade magnetite mined ore.

[12] M. A. Pertsev and S. M. Filippov. Razvitiye Chernoy Metallurgiy 1963 godu i Yeyo Osnovniye Zadachi Na 1964–65 Gode. The Development of Ferrous Metallurgy in 1963 and the Basic Program for 1964 and 1965. Metallurg, v. 9, January 1964, pp. 1–3.

Digitized by Google

The more recently planned modification of the steel production structure involves, among other things, introduction of the Thomas process for beneficiation of the large reserve of phosphoriferous ironstones of the large and easily accessible Ayat-Lisakovka ore deposits, Western Kazakhstan, as well as for similar ores of the Kerch Peninsula, on the Black Sea, none of which has been mined so far on any appreciable scale. It also involves a general increase in Martin furnace capacity of the country (the yield of steel per square meter furnace floor per 24 hours is expected to reach 8.50 tons in 1965, compared with 8.04 tons in 1963, 8.02 tons in 1962, 7.92 tons in 1961, 7.69 tons in 1960, 7.48 tons in 1959) and a wide use of electrical furnaces and oxygen converters.

The widespread utilization of ferrous scrap made possible the production of almost 40 percent more steel than pig iron, as in 1959 and 1960. On the whole, about 48 percent of ferrous scrap available to the steel industry was steel plant scrap, about 22 percent was scrap from metal fabrication plants, and the remainder was old scrap.

Regional shortages of iron and steel in Siberia and the Soviet Far East continued through 1963 and were expected to continue beyond 1965. This regional shortage will be relieved only by the commissioning of the following enterprises, still under construction: Tayshet, in Irkutsk territory, which is to be based on Korshunikha and Rudnogorsk iron ores and on Kuznetsk coal supplemented by local coal; Nerchinsk, in Zabaykal'ye, which is to be based on the ores and coal of South Yakutia; and Svobodnyy, which is to be based on the Garino and Kimkan ores and South Yakutian coal.

Nonferrous and Rare Metals.—The 1963 production quotas for traditional nonferrous metals and the so-called rare metals (including beryllium, cobalt, columbium, molybdenum, rare earths, tantalum, tin, tungsten, and possible silver) were, on the whole, fulfilled, according to Soviet reports. The total value of output of these metals was reported to have risen by 59 percent during the first 5 years of the 1959–65 plan, compared with the planned increase of 51 percent.

However accession of additional reserves of copper, lead, zinc, and tin lagged seriously behind the planned annual quotas as did the development of known resources of these minerals. The construction progress of the Kirovobad and Pavlodar alumina plants, the Krasnoyarsk aluminum refinery, the Almalyk copper smelter and refinery, the Leninogorsk zinc plant, the Ust'-Kamenogorsk titanium-magnesium plant, and the Zhdanov ore-dressing kombinat was behind schedule. These plants were scheduled or rescheduled for completion during 1964–65, the last 2 years of the current 7-year plan. Other nonferrous and rare metal plants reportedly falling behind their construction schedules included the Berezniki titanium-magnesium plant, the Tyrny-Auz tungsten-molybdenum kombinat, the Mtsensk facilities for secondary metals, and the copper ore-dressing and flotation facilities at Uchaly, Sibay, and Gay.

The new Pikalëvo alumina plant reached its full capacity only after long delay. Modernization of the tungsten-molybdenum hydrometallurgical plant in North Caucasus failed to develop as planned. In the milling of copper, the long established but recently modernized

Digitized by Google

Agarak kombinat in Armenia failed to meet its production quota, and there were indications that the Almalyk plant in Uzbekistan was not functioning efficiently. The newly organized lead facilities at the Elecktrotsink zinc plant, believed to be in Ukraine, ran into difficulties immediately after commissioning.

Technologically, excessive losses of metals continued in slags, tailings, dusts, and gases. Mechanization of mining operations, especially in the lead and zinc industry, remained unsatisfactory.

On the other hand, in 1963 the lag in completion of new mineral production capacities was offset, to some extent, by more efficient use of existing facilities. The preparation of opencast and underground mines for ore production proceeded at a pace reportedly more than satisfactory, although results might not become apparent until 1964. Meanwhile, the use of progressively greater quantities of scrap (particularly aluminum and copper) and increased production of copper ores and of nepheline concentrates as a source of alumina compensated, to some extent, production deficiencies elsewhere. The regional fuels shortage in the Urals, one of the limiting factors in the expansion of the nonferrous industry in that area, began to be alleviated at the end of 1963 when the Bukhara-Ural gasline was opened for operation. Industrial research was sufficiently advanced to introduce 130,000-ampere and larger electrolysers into the aluminum refining industry on a large scale and to expand the production of secondary aluminum in vacuum-distillation furnaces. The newly introduced electrolytic batteries in aluminum, copper, zinc, and magnesium industries were equipped with silicon semiconductor rectifiers, assuring a more efficient use of the current and a greater uniformity of the production processes. The continuous refining of lead, the carbonyl process for nickel, and the electrothermal production of silumine were ready for assimilation by the industry.

Aluminum.—With operations presumably started in early 1963, the Zaglik alunite mine in Azerbaydzhan was reported at the beginning of May to have produced its first 100,000 tons of alunite. The Sumgayit alumina plant was designed and constructed to operate on the Zaglik ores. Every 6.6 tons of alunite yield 1 ton of alumina as well as 0.5 ton of potassium sulfate and 1.15 tons of sulfuric acid. The production of alumina from Siberian nepheline syenites was deemed impractical, especially since there were definite indications of bauxite ores in Central Siberia.

In the metal sector, the Kirovobad refinery, 8 years in construction, was reported in early 1963 to be finally going on stream sometime during the year. Output of the Irkutsk refinery increased in 1963, the 2d year of its operation.

Bismuth.—As in 1962, bismuth was produced in 1963 almost entirely from complex ores, such as the tungsten-molybdenum-bismuth ores of North Caucasus, by wet metallurgy involving flotation, leaching with strong mineral acids, and subsequent precipitation or by cementation of the bismuth on iron. Bismuth of 99.9 percent purity was produced by fire refining. Scheelite and cassiterite ores of Kazakhstan and Siberia are also processed for bismuth; in these ores, the metal ranks as a coproduct of tungsten and tin.

Digitized by Google

Copper.—The Soviet domestic supply of copper in 1963 was augmented by large imports of metal from abroad, and requirements were reduced by increasingly greater use of substitutes. Domestic mine output was increased at several locations in Kazakhstan (Balkhash, Dzhezkazgan, and Boshchekul'), Ural (Gay and Uchaly), Armenia, and Siberia. The regional shortage of water in Central Kazakhstan, one of the limiting factors for the full-scale exploitation of the Dzhezgazgan copper deposits, will be alleviated by a canal under construction to bring water from the Irtysh River, some 500 kilometers east of the area. Dzhezgazgan reportedly is the largest single reserve of copper in the country and is one of the world's largest deposits of cupriferous sandstone.

Precious Metals.—Several new and efficient processes for the recovery of gold, silver, and the six platinoids from anode slimes and from low-grade materials were reported in 1963 Soviet publications. These new processes, reported as having been "patented", involve ionic exchange, chelation, liquid-liquid extraction, and other hydrometallurgical concepts. The byproduct or coproduct precious metals extracted from polymetallic ores and residues are becoming increasingly more important in the Soviet mineral economy.

Titanium.—The Soviet titanium industry has been the second largest in the world since 1958, after that of the United States. Large deposits containing ilmenite with zircon and rutile were discovered in Ukraine and Siberia in 1955. A new process of flux-less smelting briquets composed of ilmenite concentrate with 5- to 8-percent anthracite and 3-percent lye was reported. Despite an output roughly equaling the combined production of Japan and the United Kingdom, the Soviet Union must import titanium to meet the rising demand within the country. Trade data for 1963 were not yet available, but some titanium was imported from Japan in 1962.

Tungsten.—The Nal'chik plan, based on the tungsten-molybdenum ores of Tyrny-Auz in North Caucasus and apparently reconditioned in 1962, continued operations but without the expected increase in tungsten metal output. The Nal' chik hydrometallurgical plant is reported to be the only one of its kind in the U.S.S.R. and Europe. According to the same report, only one plant of its kind exists in the United States.

Vanadium.—The principal source of Soviet vanadium in 1963 continued to be the 11 percent V_2O_5 slag from the smelting of the titaniferous magnetites of the Kachkanar pits in the Ural area. However, this source of supply appeared to have been supplemented during the year by ferrovanadium produced from the ironstones of the newly opened Ayat-Lisakovka pits in West Kazakhstan.

NONMETALS

Abrasives.—Despite its technological advancement and efficiency, Soviet Union's abrasives industry remained inadequate to meet domestic demands. As a result, the country continued to be a net importer of large quantities of abrasives in 1963. During the year, two corundum factories, at Zaporozhe and Leningrad, were in operation. A third one, reportedly at Kosulino, was being reconditioned while three

Digitized by Google

additional ones were being planned, at Roslavl', Chelyabinsk, and Yurga, the latter two in Siberia.

Asbestos.—The 1965 production target for asbestos was set at roughly 1.4 million tons, presumably for all grades including two standard hand-cobbed grades (to be produced in part for export) and six standard milled grades.

Construction Materials (Natural).—In 1963 Soviet output of natural construction materials continued essentially within the ranges of the 1959–65 production targets. However, operations were carried out under the handicaps of uneven distribution of reserves, the consequent regional shortages, and the long distances over which such materials as sand, gravel, and stone must be hauled from pits and quarries to the areas for their consumption. The rail haulage for cement, averaging about 650 kilometers, was roughly twice the distance for other materials. Meanwhile, despite a 6-percent increase in production over the 1962 level, the U.S.S.R. remained a large net importer of cement.

Cement Raw Materials.—Practically all the proven reserves of basic cement raw materials (over 12 billion tons of carbonates and clays and about 3 billion tons of gypsum) are in European Russia, Ukraine, and Kazakhstan. Little if any is found in other parts of the country.

Proved reserves of lime, including limestone, total about 4 billion tons. While estimated 1963 production of both construction and technological grades of lime increased over the 1962 levels, total output remained below the 1961 record level of over 17 million tons. The original production goal for 1965 was 17 million tons.

Gypsum production in 1963 remained at about the 1962 level. The 1965 goal was originally set at 13 million tons. No gypsum deposits are known to exist in West Siberia or the Soviet Far East.

Sand, Gravel, and Stone.—Detailed data on production of sand, gravel, and stone are not available. Total output in 1963 apparently was not far above the 1956 figure, reported as 190 million cubic meters, or much more than half of the original 1965 production goal of 400 million cubic meters. Reserves have been reported as deficient in many areas. There was no evidence that discovery of new sources of supply had eased regional shortages of dimension stones, one of the critical commodities at the beginning of the 1959–65 plan. Overall reserves, in cubic meters, were reported as over 8 billion for sand and gravel, 7 billion for rocks suitable for rubble and filling, and over 800 million for dimension stones.

Glass Sand.—Few of the large deposits of quartz sand in the Soviet Union could be used without upgrading; presumably the better grade materials in these deposits have been largely depleted. As a result, most glass factories in the country continued to depend on distant sources for the supply of sand (mostly transported by rail). Output of window glass in 1963 was 169 million square meters, compared with 140 million square meters in 1959, 166 million square meters in 1962, and the target of 220 million square meters in 1965.

Diamond (Natural).—Industrial research in the flotation of diamonds continued in the Soviet Union in 1963, reportedly with encouraging results. Technologic advances in this respect might find applications in the Yakutian diamond fields of Siberia.

Digitized by Google

Feldspar.—The pattern of feldspar consumption in 1963 in the Soviet Union, much different from that of the United States, was apparently the same as during 1958–62 when 60 percent was used for glass manufacture, 30 percent for ceramics, 4 percent for abrasives, and 6 percent for other purposes.

Fertilizers (Mineral).—The original Soviet 1959–65 production plan and targets for mineral fertilizers was not affected by the poor crop yields which led to large imports of wheat from abroad. However, the urgency of attaining the 1965 production target of 35.5 million tons was reemphasized at the December 1963 CPSU Plenum. At the same time, in Soviet technical publications it was reaffirmed that the earlier understanding that high and dependable crop yields, insofar as they are contingent on the use of mineral fertilizers and on irrigation, may not be attained until 1970 or later. The unfavorable geographical distribution of the mineral base for the Soviet fertilizer industry was reappraised. The known deposits of phosphates and potassium ores of Siberia remained to be further explored. For this exploration work, the appropriation for 1963 was 2.16 million rubles, to be raised to 7.3 million rubles in 1964 and 10.5 million rubles in 1965.

New projects placed on stream in 1963 raised Soviet Union's total mineral fertilizer capacity by about 7.4 million tons. These included the Grodno nitrogenous fertilizer plant, the Soligorsk I Potassium Kombinat, and the Kengisepp phosphorite mine.

Nevertheless, it appeared that the 1965 mineral fertilizer production goal would be difficult to reach without a large expansion of the Soviet copper, lead, zinc, and aluminum industries. The combined output of mineral fertilizers at the Krasnoural'sk and the Kirovograd copper kombinats in Ural and of the Alaverdy metallurgical-chemical kombinat in Armenia was more than 400,000 tons, primarily phosphatic. Construction of a double superphosphate plant at the Sredneural'sk copper smelting enterprise was started. The first section of the plant was to have an annual capacity of 700,000 tons; output of plant was to be doubled eventually. The production of potassium sulfate, as a coproduct of alumina, was scheduled for the Kirovobad and Achinsk alumina plants; actual construction of the potassium sulfate factories had already begun. Regional shortages of pyritic concentrates in Ural were not compensated in 1963, pending construction of additional ore-dressing and flotation plants at Uchaly, Sibay, Sredneural'sk, Gay, Urup, Nikolayevsk, and elsewhere. The 1965 goal for the base nonferrous industry was to increase the output of pyrite by 70 percent, to about 6 million tons.

Nitrogen.—The bulk of nitrogen consumption in the U.S.S.R. is in the form of ammonium sulfate and ammonium nitrate fertilizers; "NPK" (nitrogen-phosphate-potash) fertilizers are mostly used in the United States. In 1963, the U.S.S.R. had 28 known nitrogen plants and 6 byproduct ammonia plants in operation, with a total estimated capacity of 1.5 million tons of contained nitrogen (equivalent to about 7.3 million tons of standard Soviet nitrogenous fertilizers). At least 14 more plants were either in construction or projected. Of the total known 1963 nitrogen capacity, about 68 percent was in European Russia, 17 percent in Ukraine, 9 percent in Central Asia, and 6 percent in Siberia; Siberia is expected to rank second and

Digitized by Google

the Ukraine fourth in relative importance when the planned output of 4 million tons of contained nitrogen is reached, apparently by about 1967.

The planned conversion of the Soviet nitrogen industry to a different raw material base gained further momentum in 1963. The combined use of coke gas, natural gas, and petroleum byproduct gas continued to increase, while that of coal and coke showed a further decline.

Phosphate.—The estimated 1963 output of phosphate ore of the Karatau basin, with two pits and one mine, was 700,000 tons (16 to 32 percent P_2O_5), or only a small fraction of the basin's capability. The Kengisepp plant in the Leningrad area increased its output of phosphorite flour containing 19 percent P_2O_5 to about 400,000 tons; output was derived from shellstone phosphorite ores containing 5 to 15 percent P_2O_5 mined by open-cast methods.

The increase of output of phosphate fertilizers in the Soviet Union in 1963 was attained largely through a better use of available capacities rather than the commissioning of new ones. Single superphosphate continued to be the basic type of phosphate fertilizer produced. The P_2O_5 content of the Khibiny and the Karatau superphosphates remained at 19 to 20 percent and 14 to 15 percent, respectively. Soviet production of Thomas slag continued at its former level of 350,000 tons, pending the planned increase to 2 million tons in 1965.

About 95 percent of the 3 billion tons of proved reserve of economic phosphate ores are equally divided between the apatite deposits in the Khibiny District of the Kola Peninsula in the extreme northwest, the phosphate rocks in the Karatau Basin of Kazakhstan, and the low-grade concretionary ores scattered in a large number of relatively small deposits on the Russian Platform. Currently exploitable ores are not found east of the Ural Range. As a result, nearly all phosphate fertilizers consumed in Siberia and the Far East is brought in from the western part of the country by rail over distances of 1,500 to 7,000 kilometers and at costs of 4 to 19 rubles per ton compared with the cost of the fertilizer itself of 17 to 24 rubles per ton.

Potassium.—The bulk of the increased output of potassium fertilizers in 1963 may be credited to the greater capacity of the Solikamsk Kombinat and the commencement of production at Starobino in Belorussia. All Soviet potassium ore reserves and all of Soviet's potassium fertilizer output occur in the European part of the country. As a result, the transportation costs, up to 19 rubles a ton, often exceed the cost of the fertilizer of 7 to 11 rubles per ton.

Fluorspar.—Flourspar was mined from open pits in Transbaykalia and the Soviet Far East with lead as a coproduct. Ores in one location were reported as 40.5 percent CaF_2 and 1.32 percent lead. Soviet Union's domestic fluorspar output remained significantly inadequate to meet demand despite the considerable reserves in the country, and recorded exports of fluorspar to Japan and of cryolite to other countries. Soviet requirements were partly met through imports of which about 80,000 tons of fluorspar were recorded in 1962.

Graphite.—As in prior years, Soviet output of natural graphite in 1963 was supplemented by high-grade material recovered from metallurgical wastes of Krivoy Rog, Azovstal', and other iron and steel

Digitized by Google

enterprises. The Zhdanov plant in Ukraine processes annually about 3,000 tons of screened scrap containing 18 to 20 percent graphite.

Kaolin.—Output of kaolin in the Soviet Union in 1963 was at about the 1957 level. More than 80 percent of this output came from the high-grade Ukrainian deposits. The remainder, all low-grade material unsuited for the paper industry, was obtained almost entirely from the Ural region.

Mica.—As in prior years, muscovite was produced at Malinovaya Varaka and four other mines on the White sea and in two high-grade mines in the Mama District in Yakutia in Siberia. The Aldan phlogopite mica district, also in Yakutia, was reported by the Soviets to have the world's largest reserves of this type of mica. Strategic-grade mica continued to be imported to meet special demands.

Sulfur and Pyrite.—The Soviet Union's largest sulfur deposit, Razdol'skoye, is in the western part of the Ukraine. This deposit, with estimated reserves of 10 million to 30 million tons of elemental sulfur, was not mined on any significant scale until 1961. However, the Razdol'skoye Sulfur Kombinat probably attained an annual capacity of 600,000 tons of contained sulfur in 1963, 2 years ahead of schedule, and further expansion was underway.

The planned increase of sulfur output from the Gaurdak dome to five times the 1962 level may have been achieved in 1963. The total output from this relatively small deposit in Tadzhikistan and other even smaller deposits in European Russia and Central Asia probably amounted to less than 100,000 tons in 1963.

In the Soviet nonferrous smelters, sulfur is either entirely wasted or only partially recovered. In 1963 only five out of the total of nine copper smelters in the country used their sulfur gases for the production of sulfuric acid, and the sulfur recovery was only 32 percent. Zinc smelters were able to recover 72 percent of the sulfur from waste gases, but apparently recovery operations were undertaken in Eastern Kazakhstan only. Sulfur recovery at the lead smelters was negligible and at the three nickel smelters nil; the waste at the latter operations alone was equivalent to 1.5 million tons of sulfuric acid. Plans to reduce gas wastes in 1963 were not fulfilled reportedly because of poor management and lack of control and cooperation on the part of technologists and engineers.

In 1963 pyrites accounted for about 62 percent of Soviet Union's sulfuric acid production, elemental sulfur 20 percent, and waste gases 18 percent. Current plans call for the contribution of waste gases to increase to 39 percent of the total by 1965. In terms of production by facilities, only a quarter of the total sulfuric acid output was produced by the country's nonferrous metallurgical enterprises from their own pyrites and waste gases. The remainder of their pyrite supply was shipped to sulfuric acid plants elsewhere or discarded. The Ural alone shipped more than 4 million tons of pyrites in 1963 to sulfuric acid facilities in Ukraine and the industrialized center and northwest of European Russia.

Synthetic Crystal Industry.—The Soviet Union apparently continued research in the field of synthetic crystal production and use. Since the 1950's, metal crystals, metal-organic crystals, and organic crystals have been produced, although quantitative data are not available. Notable

TABLE 8.—Salient sulfur industry statistics [1]

(Thousand metric tons)

Commodity	1959	1960	1961	1962	1963
Sulfur:					
Produced from ore except pyrite	600	800	850	950	950
Content of pyrite	1,350	1,400	1,450	1,400	1,500
Recovered from gases	200	200	300	350	400
Total	2,150	2,400	2,600	2,700	2,850
Sulfuric acid production (as $H_2SO_4 \cdot H_2O$):					
From sulfur from ore	950	1,050	1,150	1,250	1,400
From pyrite	3,582	3,798	3,778	3,882	4,300
From sulfur from gases	550	550	800	1,000	1,200
Total	5,082	5,398	5,728	6,132	6,900

[1] Total sulfuric acid production is reported; all other data are estimates.

products of the industry include monocrysts of quartz, gemstone, fluorspar, Iceland spar, germanium, and others. At least one synthetic industrial diamond factory apparently has been in operation in Saratov for some time.

Talc.—The 1965 production goal for talc in the Soviet Union was set at 514,000 tons, nearly a 140-percent increase over the 1963 estimated output. About two-thirds of the talc consumed in the country is for insecticides, 9 percent for paper, 5 percent each for rubber manufacturing and roofing, and the balance for other miscellaneous uses. The country continued to import substantial quantities of high-grade talc.

Vermiculite.—The vermiculite reserve of Eno-Kovdor in Kola Peninsula, the largest in the country and apparently the only one exploited, was reported as 2.45 million tons. This figure included 1.2 million tons of top-grade material.

MINERAL FUELS AND ENERGY

The planned changes in the fuels production structure and the eastward shift of the production of fuels, particularly of coal continued in 1963.

TABLE 9.—Changes in fuels production structure (as percent of total production recalculated as standard fuel)

Fuel	1958	1960	1962	1963	1965 (planned)
Coal	58.8	53.9	48.8	46.0	43.4
Shale	.7	.7	.7	.8	.7
Peat	3.4	2.9	1.7	2.5	2.7
Wood	5.3	4.1	3.7	3.4	1.8
Oil	26.3	30.5	34.2	34.9	33.8
Natural gas (including byproduct gas)	5.3	7.9	10.9	12.4	17.5

While the share of coal in the fuels balance of the country was decreasing progressively, the tonnage output of coal continued to rise, particularly in the eastern coal basins. During 1958–63, the output of the Donets Basin increased by 6 percent, of the Kuznetsk by 19 percent,

Digitized by Google

of the Karaganda by 14 percent, of the Ekibastuz by 61 percent, of Central Asian mines and pits by 14 percent, of East Siberia by 15 percent, and of the Far East by 22 percent.

As the result the percentage output of coal basins east and south of the Ural Range rose to 38 of the U.S.S.R. total, compared with 34 in 1958.

The largest increase in the production of oil and gas occurred in Tataria, Bashkiria, and the Kuybyshev District. The 1963 output of gas in Uzbekistan (the Gazli fields representing 25 percent of the U.S.S.R. total reserve of natural gas) was 23 times as high in 1963 as in 1958.

Total production of hydroelectrical power increased by 55 percent (1958–62); however, production in Siberia, the Far East, Central Asia, and Kazakhstan increased by 68 percent. These regions contain 85 percent of the reserve of hydroelectrical power and 75 percent of total fuels reserve. The 1962–63 output of hydroelectrical power in these eastern areas rose from 19.7 percent of the U.S.S.R. total in 1958 to 21.3 percent in 1962; the estimated percentage for 1963 is close to 22.

However, the greater part of increased output of electrical power was credited mainly to the thermoelectrical power stations.

In 1962, 73 percent of the total power capacity and 83 percent of the power output was in regional high-capacity power stations; industrial power stations had 17 percent of the capacity and accounted for 14 percent of the output; while communal, transportation, agricultural and other unspecified plants provided the balance.

In 1962, and in 1963, by preliminary indications, 21 percent of the total fuel of all kinds expended in the U.S.S.R. was used for the production of electrical or motive energy including 7 percent in industrial power installations, 8 percent in railway locomotives and transport vessels, and 6 percent in other kinds and means of transportation.

TABLE 10.—Increase in the output of electrical power in 1958 and 1960–63, as percent of the output of 1958

Type of power station	1958	1960	1962	1963 [1]
Thermoelectric	100	128	157	178
Hydroelectric	100	110	155	163
All types	100	124	157	175

[1] Preliminary data.

Almost 44 percent of all natural fuels used in the U.S.S.R. required upgrading or refining. Specifically, such processing is applied to 20 percent coal, 41 percent shale, 12 percent peat, 99 percent petroleum, more than 5 percent natural gas.

The country's industries consume two-thirds of the country's total fuel and more than three-fourths of its total electrical and thermal energy. The industries consume 69 percent of all coal, 99 percent of shale, 83 percent of natural gas, and 70 percent of fuel oil.

Digitized by Google

While the rail freight turnover was 9 percent higher in 1962 than in 1960 and passenger traffic was 11 percent higher, the railroad consumption, as standard fuel, decreased by 18 percent. The saving of 23 million tons of coal was particularly important for the economy. The accompanying increase in the consumption of electrical power was equivalent to about 2.5 million tons standard fuel.

In 1962, 38 percent of all haulage by rail (including passengers) was by steam engines which consumed 80 percent of the total fuels allocated to the railways. In the same year, diesel engines hauled 32 percent of all freight (and passengers) and consumed only 9 percent of the total railways fuel, while the balances of haulage and fuel consumption were accounted for by electric engines.

TABLE 11.—Utilization of fuels by type and purpose (percent of total consumed)

Fuel	Production of electrical energy	Production of thermal energy	Production of mechanical energy	Conversion into other fuels and purposes other than fuel production [1]	Technology and miscellaneous
Coal	29	23	11	20	17
Shale	38	16	----	41	5
Peat	39	31	1	12	17
Wood	4	10	5	3	78
Oil	0.1	0.3	----	99.2	0.4
Natural gas (including byproduct gas)	23	32	2	5	38
Fuel oil (mazut)	11	32	26	1	30
Diesel fuel	16	1	71	1	11
Gas from coke	7	11	2	5	75
Gas from blast furnaces	10	16	4	----	70

[1] Including petrochemical production and similar uses.

TABLE 12.—Consumption of total fuels and energy by different sectors of the national economy in 1962

(Percent)

Sector	Fuels	Energy	
		Electrical	Thermal
Industries	67	77	77
Construction	2	3	4
Agriculture	6	4	1
Transportation	13	7	3
Household, communes, etc.	7	6	9
Other	5	3	6

In 1962, the primary (natural) fuels-energy resources of the U.S.S.R. increased by 30 percent since the end of 1958 (including the 55-percent increase in the hydroelectrical power). Recalculated on the standard fuel basis, these resources represent the annual output of 906 million tons of fuels plus the 9 million tons equivalent of the hydroelectrical power (1 percent of the total).

The experience of 1962 shows, however, that about 34 million tons standard fuel were freed per every kilowatt-hour per year of hydroelectrical power consumed. Thus the share of the hydroelectrical power in the energy balance of the country may be reckoned as about 3.5 percent.

Digitized by Google

As it is the utilization of fuels by combustion, for the production of energy was only 40 to 45 percent efficient.

The first atomic power station, 5,000-kilowatt capacity, was put into operation in June 1954, at Obninsk, in the Kaluga area. The second one, in Siberia, was commissioned in 1958. In 1963, the first section of the Belyy Yar station (105,000 kilowatt), Sverdlovsk area, went into operation. At least two more stations were commissioned in 1962–63.

In 1963, the Novo-Voronezh station, 210,000-kilowatt capacity; the Melekess station, near Ul'yanovsk, 70,000-kilowatt capacity; and a certain number of smaller atomic power stations were in construction. In 1963, two motorized atomic power stations were built and commissioned for operation.

New energy developments in 1963 included the oilfields in the Tyumen' territory, in the West-Siberian Lowland, where the first oil was struck in 1960, were reportedly proved to contain economic reserves of billions of tons, large enough to call this region "the Third Baku." The known natural gas reserves in the same region were reported as trillions of cubic meters. The newly discovered and appraised fuel shales at Kenderlyk, Eastern Kazakhstan, whose tars yield 25 percent gasoline and 36 percent diesel oil, were rated the highest grade shales in the U.S.S.R., Europe, and United States. The geographically associated coal reserve is reported as at least 1.5 billion tons. The hydroelectric power resource of Siberia is now rated at 1,500 billion kilowatt-hours, 180 billion of which is in the Yenisey-Angara Basin. The resource of Central Asia exceeds 450 billion kilowatt-hours.

A new trunk gasline, Bukhara-Ural, 2,000 kilometers long was completed in 1963, and its first string (1,020 millimeter pipe) will deliver about 7 billion cubic meters of gas in 1964. The Ordzhonikidze-Tbilisi trunk gasline was commissioned in 1963.

The Mineral Industry of the United Kingdom

By Justin B. Gowen [1]

EARLY in 1963 the general economy of the United Kingdom took an upturn which by yearend had penetrated nearly all sectors of industry, including mineral producing and processing, and led some sectors to record rates of production. Contributing to the improvement were certain fiscal measures inaugurated by the Government to stimulate consumer demand in the basic industries. These included reduction in excise taxes, favorable changes in amortization allowances, and easement of credit regulations for shipbuilding and industrial development projects. Notable improvements in the mineral-based industries were the rises in production of iron and steel and the metal manufacturing industries after the prolonged depression which followed the peak year of 1960.

Except for domestic iron ores, which supplied about one-third of the iron-in-ore requirements of the iron and steel industry, Cornish tin ores which supplied 5 to 6 percent of the tin metal requirements, and a small tonnage of lead and zinc concentrates recovered from old dumps and from the beneficiation of barite and fluorspar, mineral production in 1963 was limited to the nonmetallic minerals, construction materials and fuels sectors.

In 1962 the United Kingdom was first in world output of strontium minerals (celestite), probably second in the production of china clay, and ranked high in the world production of salt, gypsum and anhydrite, diatomite, barite, fluorspar, cement and other construction materials, and coal.

The British nonferrous metal industries continued to be almost entirely dependent on imported raw materials and domestic scrap. On a world basis the United Kingdom ranked 3d in the production of tin metal, 6th in refined lead, 9th in refined copper, 10th in slab zinc, and was a leading producer of aluminum.

Celestite, the clays, salt, and coal were the only significant exports from dometsic resources.

Of the 1963 gross domestic product, reported to be nearly US$73 billion, industrial production contributed somewhat less than half, with mining and quarrying accounting for about 2.8 percent, the metals industries 3 percent, and other mineral-based industries including chemical elements and compounds and nonmetallic mineral

[1] West Europe specialist, Division of International Activities.

Digitized by Google

products about 9 percent. Of the total employed population at year-end 1963 reported at about 25,109,000 persons, 670,000 or 2.7 percent were employed in the mining and quarrying industries and 607,000 (2.4 percent) in the metals industries.

Imports of all goods for consumption in 1963 increased by about 7.8 percent over imports in 1962 and were valued at US$13,066 million, of which US$3,329 million or 25.5 percent was in mineral and metal products. Exports of all produce and manufactures of the United Kingdom during 1963 were about 7.6 percent above 1962 exports and were valued at US$11,424 million of which US$2,312 million was in minerals and metals. Petroleum led the imports while iron and steel led the exports.

GOVERNMENT POLICIES AND PROGRAMS

In general, minerals are the property of the owner of the surface above them, and are subject to laws governing the surface. Excepted are coal, atomic energy materials, and petroleum. The extraction and working of minerals is also subject to regulation under provisions of the Town and Country Planning Act of 1947.

The ownership of coal and the right to work it are vested in the National Coal Board under provisions of the Coal Industry Nationalization Act, 1946. The Minister of Supply is responsible for the acquisition of atomic energy materials under provisions of the Atomic Energy Act of 1946.

Ownership of petroleum resources is vested in the Crown, and applications for their development are administered by the Ministry of Power. Rights can be held only by British subjects or companies organized in the United Kingdom, of which at least one director and a majority of the employees are British.

Under the Iron and Steel Bill (1949) all companies in the iron and steel industry having a minimum annual production of 50,000 tons of iron ore, or 20,000 tons of pig iron, crude steel, or rolled products, became subject to nationalization, and their assets were acquired by the Iron and Steel Corporation of Great Britain. Smaller companies, with a minimum production of 5,000 tons annually of any of the above products were made subject to regulation through license. The Iron and Steel Bill (1949) was repealed by the Iron and Steel Act, 1953, and assets of the nationalized companies, 71 major companies with 231 subsidiaries, were transferred to the Iron and Steel Holding and Realization Agency for return to private ownership. At the end of 1963 only one company, Richard Thomas and Baldwins, remained under control of the Government agency.

The Iron and Steel Act, 1953 (Part II, Sec. 3), also provided for the establishment of the Iron and Steel Board consisting of 9 to 14 members whose duties were—

> . . . to exercise a general supervision over the iron and steel industry, and to such extent as they may consider necessary the powers conferred on them by this Act, with a view to promoting the efficient, economic and adequate supply under competitive conditions of iron and steel products, and in particular to keep under review:

Digitized by Google

(a) The productive capacity of iron and steel producers;
(b) The arrangements for procuring and distributing raw materials and fuel for use in the iron and steel industry;
(c) The prices charged for iron and steel products;
(d) The arrangements for the promotion of research relating to the iron and steel industry and of the training and education of persons employed or to be employed in the industry;
(e) The arrangements for the promotion of the safety, health and welfare of persons employed in the iron and steel industry; and
(f) The arrangements for joint consultation between iron and steel producers and persons employed by them in the iron and steel industry or representatives of such persons on matters of mutual interest other than terms and conditions of employment.

In 1963 the board consisted of three full-time and eight part-time members drawn from trade unions and producers and consumers of iron and steel. The Board is consultative and advisory but also has specific duties, where the National interest is concerned, and the powers needed to carry them out. It is financed by levies which it is empowered to make on industry.

The nationalized industries, which include coal, electricity, gas, and the railroads, are administered by executive agencies. Although the Government has no direct control over prices in these industries, it exercises a considerable influence where the public interest is concerned.

In 1961 the responsibility for developing policies in certain spheres contributing to more rapid and sustained economic growth of the United Kingdom was given to the newly established National Economic Development Council (NEDC). The Council in turn established the National Economic Development Office (NEDO) to study the implications for the United Kingdom of a 4 percent annual growth rate between 1961 and 1966 based on the prospects of 17 industries including the mineral-based coal, gas, electricity, chemicals, construction, iron and steel, petroleum, heavy electrical machinery, machine tool, and motor vehicle industries. These studies were still in progress at yearend.

PRODUCTION

Preliminary figures show little variation in the gross value of production from mines and quarries in 1963 compared with that of 1962. Gross production of nonferrous metals also showed little change from that of 1962, but the output of refined aluminum, cadmium, lead, and slab zinc was higher than for any previous year, while copper output continued to decline from its 1961 high.

TABLE 1.—Production of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Mineral fuels—Continued					
Finished refinery products:					
Butane and other petroleum gases thousand 42-gallon barrels	3,127	4,640	5,417	7,453	10,933
Aviation gasoline do	12,442	11,618	11,868	13,278	7,507
Motor spirit do	53,177	57,294	60,829	60,684	58,776
Other white spirit do	1,223	1,441	1,358	1,296	1,348
Kerosine do	13,949	17,972	21,117	20,541	24,262
Gas-diesel oil do	54,885	57,969	65,318	75,542	81,773
Fuel oil do	105,604	125,467	143,186	148,685	143,129
Lubricating oils do	6,143	6,484	6,809	6,390	6,877
Bitumen do	5,921	6,387	6,985	7,517	8,042
All other products thousand tons	962	1,419	1,418	2,238	2,852

[1] Data not available.
[2] Does not include refined from imported bullion.
[3] Estimate.
[4] Includes feldspar and perlite.

TRADE

Distribution of the value of imports for consumption and exports of United Kingdom produce and manufactures in the various mineral and metal groups in 1963 were as follows:

Commodity group	Value (million U.S. dollars)			
	1962		1963	
	Imports[1]	Exports[2]	Imports[1]	Exports[2]
Metals:				
Metalliferous ores and scrap	388	56	400	46
Iron and steel	149	560	210	573
Nonferrous metals	632	369	623	348
Metal manufactures, not elsewhere specified	82	385	86	371
Nonmetals:				
Chemical elements and compounds[3]	180	232	211	259
Crude fertilizers and crude minerals (excluding fuels)	107	42	109	50
Fertilizers, manufactured	50	13	56	14
Nonmetallic mineral manufactures, not elsewhere specified	58	187	65	190
Fuels and energy:				
Coal, coke and briquets	2	87	2	134
Gas and electric energy	1		2	1
Petroleum and petroleum products	1,484	322	1,565	326
Total	3,133	2,253	3,329	2,312

[1] Does not include imports which were reexported.
[2] Does not include reexports.
[3] Includes some metals, generally those recovered by chemical methods.

Geographical and political distribution of imports to and exports from the United Kingdom of the listed commodities shows that the British Commonwealth led other country groups as a source of supply, accounting for US$894 million in value or 26.8 percent of the total. Next in importance were the European Economic Community countries (ECC) which supplied imports with a total value of US$500 million or about 15 percent of the total, and the European Free Trade

Digitized by Google

Area (EFTA) which accounted for US$213 million or 6.4 percent of the total. Individually, Kuwait, which supplied US$427 million in value, representing 27 percent of all petroleum products imported by the United Kingdom during 1963, led all other nations and was followed by Canada which supplied US$350 million in imports and the United States which supplied products valued at $214 million.

As a market for U.K. mineral and metal products the European Economic Community was first, receiving US$571 million in value of U.K. exports, and the European Free Trade Area was second with US$383 million. Individually, the United States was the U.K.'s best customer, receiving products valued at US$148 million, followed by Sweden with US$145 million and West Germany with US$135 million.

TABLE 2.—Value of mineral and metal trade by area and country in 1963

(Million U.S. dollars)

Area and country of origin and destination	Imports [1]			Exports		
	Minerals and metals	Fuels	Total	Minerals and metals	Fuels	Total
British Commonwealth:						
Australia	58	(2)	58	83	3	86
Canada	350	(2)	350	97	3	100
India	11	1	12	59	6	65
Nigeria	1	48	49	33	1	34
Rhodesia and Nyasaland	158	(2)	158	11	(2)	11
Trinidad	2	72	74	13	1	14
Other	70	123	193	242	15	257
Total	650	244	894	538	29	567
European Economic Community (EEC):

TABLE 3.—Exports [1] of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum:			
Alumina and aluminum hydroxide	24,211	16,079	(2).
Aluminum-and aluminum alloys:			
Unwrought	5,495	5,465	
Semimanufactures:			
Bars, rods, angles, shapes and sections.	4,008	3,566	Canada 11,038; United States 6,768; Ghana 5,216; Sweden 3,910; India 3,757; Australia 3,611.
Plates and sheets	42,211	48,080	
Foil	6,194	6,577	
Other	1,605	1,904	
Arsenic, white	6,883	8,297	(2).
Bismuth—kilograms	388,320	519,215	(2).
Chromium—do	319,921	275,460	(2).
Copper and copper alloys:			
Unwrought: Refined	79,465	123,341	Belgium 43,183; West Germany 13,808; Poland 13,274; East Germany 10,136; Netherlands 7,200.
Including reexports	7,115	12,609	
Brass and bronze ingots	38,169	41,287	(2).
Semimanufactures:			
H.C. wire rods	17,760	17,797	(2).
Other copper	20,428	17,334	(2).
Brass and bronze	33,319	25,660	(2).
Nickel silver and cupro-nickel	1,771	1,986	(2).
Gold:			
Bullion, fine gold troy ounces content.	24,604,143	28,966,563	(2).
Gold coin—do	948,866	761,037	(2).
Semimanufactures, 9 carats or better (excluding jewelry). do	23,591	20,285	(2).
Iron and steel:			
Scrap—thousand tons	30.1	1,102.3	Italy 278.1; Spain 245.7; Japan 225.4; West Germany 118.1.
Pig iron—do	147.4	222.9	West Germany 74.8; Japan 51.5; Switzerland 24.1.
Ferroalloys—do	5.7	6.2	West Germany 1.2; Netherlands 0.8.
Steel ingots and other primary forms. do	105.0	86.7	Venezuela 27.1; Argentina 15.5; Greece 9.8.
Finished steel:			
Bars, rods, angles, shapes and sections. do	743.4	671.6	United States 75.5; U.S.S.R. 64.8; New Zealand 47.8; India 36.8 Canada 36.1; Netherlands 32.0.
Plates and sheets:			
Uncoated:			
3 mm thick and over. do	423.7	398.9	Norway 56.0; France 41.2; Sweden 33.9.
Less than 3 mm—do	416.2	559.1	U.S.S.R. 130.6; Sweden 64.9; West Germany 57.0; Italy 39.8.
Coated:			
Tinplate and tinned sheets. do	434.5	465.1	Republic of South Africa 42.8; Argentina 37.3; United States 36.7.
Other—do	112.1	111.4	Finland 16.2; British West Indies 7.2.
Hoop and strip—do	107.6	98.0	India 11.6; Australia 5.6; Sweden 5.3.
Railway material:			
Wheels, tires, and axles. do	40.9	48.3	Republic of South Africa 14.7; Mexico 4.7; Pakistan 4.1.
Rails and other track material. do	182.9	124.8	Italy 12.5; Tanganyika 12.3; Iraq 11.0.
Wire, single strand not insulated. do	131.0	113.6	United States 21.0; Canada 13.2; India 9.2; New Zealand 9.2.
Tubes, pipes and fittings:			
Wrought—do	527.5	433.3	United States 88.4; British West Indies 30.5; Canada 27.0.
Cast—do	116.2	103.5	Sweden 8.5; Canada 6.5; Iraq 5.5; British West Indies 5.4.
Rough forgings—do	1.9	2.2	Sweden 1.0.
Total iron and steel (excluding scrap). do	3,496.0	3,445.6	

See footnotes at end of table.

TABLE 3.—Exports [1] of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals—Continued			
Lead:			
Bullion and refined	26,955	33,078	West Germany 19,969; Belgium 8,323; Egypt 1,942; U.S.S.R. 412.
Including reexports	626	489	
Lead alloys, including type metal	2,119	3,641	(2).
Semimanufactures, lead and alloys	2,892	2,093	(2).
Magnesium, and magnesium alloys, unwrought and semimanufactures.	1,836	2,045	(2).
Mercury, reexports—76-pound flasks	8,385	5,774	Poland 1,082; Finland 649; India 570; Republic of South Africa 512.
Nickel and nickel alloys:			
Unwrought	22,269	20,452	(2).
Semimanufactures	5,879	5,636	(2).
Platinum and platinum group:			
Platinum:			
Ingots, bars, troy ounces grains, powder, or sponge.	307,461	253,320	(2).
Other, including alloys do and semimanufactures.	39,616	58,018	(2).
Other platinum group metals do and alloys.	360,471	259,998	(2).
Silver and silver alloys:			
Silver bullion do	11,394,246	19,794,688	(2).
Other unwrought and semi- do manufactures.	6,409,464	7,474,272	(2).
Tin and tin alloys:			
Refined tin long tons	12,184	8,026	United States 1,407; Netherlands 544.
Including reexports do	2,385	870	(2).
Solder do	1,206	1,551	(2).
Antifriction metal do	553	653	(2).
Other unwrought or semi- do manufactured.	301	468	(2).
Zinc and zinc alloys:			
Slab zinc	2,318	9,509	Sweden 3,749; Brazil 1,200; Italy 1,016; Turkey 698.
Including reexports	150	2,370	(2).
Semimanufactures	6,056	7,349	(2).
Nonmetals:			
Asbestos:			
Crude fiber and waste	7,127	7,173	(2).
Manufactures	32,980	30,160	Sweden 2,984; Netherlands 1,982; Norway 1,908; Italy 1,694; Belgium 1,612.
Clay and clay products:			
Ball clay thousand tons	222.0	246.4	(2).
China clay do	1,135.4	1,118.3	(2).
Other clays do	68.5	65.2	(2).
Refractory construction ma- do terials.	147.8	128.9	(2).
Gypsum and anhydrite do	13.0	7.6	(2).
Pigments, earth	5,965	5,729	(2).
Salt:			
Evaporated thousand tons	250.6	253.2	(2).
Other do	78.4	71.8	(2).
Strontium minerals (celestite)	6,602	2,638	(2).

See footnotes at end of table.

TABLE 3.—Exports[1] of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Mineral fuels:			
Coal—thousand tons	5,686.8	4,786.6	Netherlands 1,311.9; France 790.4; Denmark 686.4; Ireland 570.0; West Germany 442.7.
Hard coke—do	504.8	695.3	Sweden 151.6; Finland 98.6; Portugal 91.6; Denmark 90.8; Venezuela 80.2.
Gas coke and coke breeze—do	998.4	1,059.4	Norway 510.3; Denmark 234.0; Sweden 98.8.
Coal tar pitch—do	172.3	213.4	(2).
Petroleum and petroleum products:			
Carbon black—do	49.4	38.4	(2).
Crude thousand 42-gallon barrels or partly refined.	815	7,368	(2).
Gasoline, including blending agents.—do	12,813	14,693	Sweden 3,788; Denmark 3,541; Norway 1,577; France 1,274; West Germany 559.
Other white spirit—do	361	415	(2).
Kerosine—do	6,468	6,555	(2).
Gas oil—do	15,658	20,492	Sweden 12,161; Netherlands 8,220; Denmark 6,784; West Germany 6,094; Norway 5,408.
Diesel oil—do	2,219	2,958	
Residual fuel oils—do	15,735	21,743	
Lubricating and other heavy oils.—do	3,519	3,666	Australia 319; India 224; Belgium 224; Republic of South Africa 214; West Germany 190.
Lubricating greases—thousand tons	32.9	33.4	(2).
Asphalt—do	63.6	69.0	(2).
Electric energy.—thousand kilowatt hours	----------	15,204	(2).

[1] Products and manufactures of the United Kingdom except where otherwise noted.
[2] Data not available.

TABLE 4.—Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962
Metals:			
Aluminum and aluminum alloys:			
Bauxite and concentrates	401,355	432,705	(1).
Scrap	5,804	8,572	(1).
Unwrought	238,938	255,276	Canada 156,742; Norway 52,356; United States 32,130; U.S.S.R 8,827.
Semimanufactures	21,527	22,189	(1).
Antimony ore, concentrate, and crude antimony.	11,921	12,330	(1).
Arsenic, white	8,740	6,688	(1).
Bismuth:			
Metal—kilograms	225,547	537,336	(1).
Alloys—do	345,911	353,684	(1).
Cadmium—do	1,172,467	1,195,839	(1).
Chromite	261,047	118,383	(1).
Cobalt—kilograms	1,439,399	1,264,040	(1).
Columbium-tantalum ores	721	796	(1).
Copper and copper alloys:			
Copper and alloy scrap, and alloy ingots.	2,088	2,511	(1).
Blister	141,965	105,653	Chile 45,585; Northern Rhodesia 39,181; Peru 20,887.
Electrolytic	358,245	399,240	Northern Rhodesia 193,293; Canada 39,096; United States 48,331; Chile 33,150; West Germany 20,673.
Fire refined	36,084	30,891	Chile 26,503.
Semimanufactures	4,437	3,990	(1).

See footnotes at end of table.

TABLE 4.—Imports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962
Metals—Continued			
Gold:			
Ores, concentrates, troy ounces—jewellers sweepings, etc. estimated gold content.	49,900	59,600	(1).
Bullion, unrefined and refined, fine gold content. troy ounces	50,786,396	34,082,175	(1).
Gold coin troy ounces	10,999	554,929	(1).
Iron and steel:			
Iron ore and concentrate thousand tons	15,206.3	13,120.0	Sweden 4,177.7; Canada 1,718.7; Algeria 1,428.3; Venezuela 1,247.1; Liberia 753.8.
Iron and steel scrap do	23.1	4.6	West Germany 2.9.
Sponge iron do	5.6	6.0	Sweden 5.9.
Pig iron do	33.1	135.6	U.S.S.R. 56.0; Norway 49.6; West Germany 10.9.
Ferroalloys:			
Ferrochromium do	43.2	25.1	Norway 62.0; Republic of South Africa 31.6; Canada 26.2.
Ferromanganese do	42.7	44.9	
Ferrosilicon do	86.6	76.8	
Silico-manganese do	26.9	25.8	
Other ferroalloys do	5.3	5.2	
Steel ingots and other primary forms. do	107.7	159.3	Canada 61.9; U.S.S.R. 54.0; Republic of South Africa 16.5.
Coils for rerolling do	90.7	269.8	U.S.S.R. 198.5; Netherlands 26.2; Canada 24.7.
Finished iron and steel products:			
Wire rod thousand tons	21.5	23.3	Sweden 9.0; Belgium 6.2; France 2.6.
Other bars and rods do	41.2	95.4	Belgium 32.7; France 18.6; Republic of South Africa 16.5.
Angles, shapes and sections. do	7.2	8.1	Belgium 1.7; Norway 1.2; United States 1.2.
Plates and sheets:			
Uncoated:			
8 mm thick and over. do	9.6	30.2	Republic of South Africa 21.0; Sweden 3.8.
Under 3 mm thick. do	143.2	153.6	Netherlands 113.8; Republic of South Africa 16.0; Belgium 6.5.
Coated do	8.5	10.3	Canada 4.3; Republic of South Africa 2.5; United States 1.8.
Hoop and strip do	6.6	10.8	Canada 4.2; United States 2.4; West Germany 1.5.
Wire, single strand not insulated. do	5.5	4.9	Sweden 2.0.
Tubes, pipes and fittings do	18.6	15.4	Sweden 7.8; West Germany 2.5; United States 1.9.
Other do	1.5	1.9	
Total iron and steel (excluding scrap).	705.2	1,102.3	
Lead:			
Ore and concentrate, lead content	23,307	27,075	Australia 20,219; Canada 3,361.
Scrap, lead and alloy	900	2,138	(1).
Bullion	49,050	47,237	Australia 113,360; Canada 40,391; Spain 11,563; U.S.S.R. 7,027; Mexico 4,778.
Refined	134,326	136,573	
Magnesium and magnesium alloys, unwrought.	5,973	5,651	(1).
Manganese ore	478,550	348,200	India 100,700; Republic of South Africa 96,630; U.S.S.R. 81,390; Ghana 26,720.
Mercury 76-pound flasks	27,047	20,725	(1).
Molybdenum ore and concentrate	8,100	5,604	(1).
Nickel:			
Mattes and speiss	63,980	54,574	(1).
Scrap	2,966	2,389	(1).
Nickel and nickel alloys unwrought	24,753	13,618	(1).
Semimanufactures	4,909	4,229	(1).
Platinum and platinum-group metals:			
Ore and concentrate	2,757	2,310	(1).
Metal and alloys, unwrought and semimanufactured. troy ounces	102,749	100,775	(1).

See footnotes at end of table.

[3] Includes products with a reported value of US$2,291,000.
[4] Includes products with a reported value of US$9,199,000.

COMMODITY REVIEW

METALS

The United Kingdom is a large processor and consumer of both ferrous and nonferrous metals. The ferrous metals industry is based partly on domestic raw materials and partly on imports. Details on raw material supplies for the ferrous industries are given subsequently under iron and steel. The domestic nonferrous metal smelting and refining industry is based almost exclusively on imported raw materials, but output is not sufficient to meet requirements of the metal manufacturing industry, making significant imports of most refined nonferrous metals necessary. Approximately 56 percent of total refined aluminum consumption, 58 percent of refined copper consumption, 29 percent of refined lead consumption, 36 percent of refined tin consumption, and 62 percent of refined zinc consumption was provided by imports of refined metal. The share of total consumption of these five major nonferrous metals derived from imported refined metals was nearly 53 percent.

Aluminum.—The United Kingdom's output of primary and secondary aluminum in 1963 was a record high, while the consumption (as measured by delivery to the fabricating and manufacturing industries) was second only to the peak year of 1960. At yearend the annual capacities of the major sectors of the British aluminum industry were—alumina 120,000 tons, primary aluminum 37,500 tons,

secondary aluminum 133,500 tons, and fabricated products about 512,000 tons. British Aluminium Company, Ltd., was the sole producer of alumina and primary metal and was the leading producer of semifabricated products.

Imports of bauxite in 1963 amounting to 336,755 tons were 22 percent below imports in 1962, while imports of aluminum metal in all forms showed an increase of 7 percent and consisted of scrap 9,368 tons, unwrought metal and alloys 296,233 tons, and semifabricated products 25,649 tons. The principal sources were—Canada 147,700 tons, United States 49,831 tons, Norway 45,737 tons, and U.S.S.R. 14,630 tons.

Exports amounted to 7,575 tons of unwrought metal and 56,722 tons of semifabricated products. The largest tonnages were consigned to Ghana (7,262 tons), Canada (5,915 tons) and Sweden (4,471 tons).

Aluminium Corporation	Dolgarrog	do.	10,000

Copper.—Refined copper production during 1963 was 7.6 percent less than in 1962 and 10 percent below the 1961 high. Production was derived from blister, all of which was imported, and from scrap, most of which was of domestic origin. However, domestic refineries supplied only 38 percent of the 557,968 tons of refined copper consumed in semimanufactures and castings. An additional 130,865 tons of scrap was used in the production of semis, castings and copper sulfate. The total consumption of copper in industry represented an increase of 4 percent over 1962 but was 6 percent below 1960, the peak year for consumption.

The principal copper producer was British Copper Refiners, Ltd., which had a capacity nearly double that of second ranked Elkington Copper Refiners, Ltd.

TABLE 7.—Principal copper producers in 1963

Company	Location of works		Refining method	Capacity (metric tons)
	Town	County		
British Copper Refiners, Ltd.	Prescott	Lancashire	Fire and electrolytic.	120,000
Elkington Copper Refiners, Ltd.	Walsall	Staffordshire	do.	66,000

Iron and Steel.—*Iron Ore.*—Production in 1963 declined about 2 percent from the 1962 level and nearly 13 percent from the 1960 high.

Digitized by Google

Consumption of home ore showed a parallel decrease, reflecting an increase in the ratio of imported ore to home ore consumed, which was roughly 2:1 based on the iron content of all ores consumed in iron and steelmaking. As in recent years, the great bulk of the domestic production came from the Northampton Sand Ironstone bed (53 percent of the total) and the Frodingham Ironstone bed (35 percent of the total), the principal deposits of the Humber-Severn Belt. This iron ore belt, extending south from the River Humber, vicinity of Scunthorpe, to Banbury, Oxford includes the Frodingham, Claxby, Lincoln, South Lincolnshire, Rutland, Leicester, Northampton, and Oxford ore fields which together accounted for more than 96 percent of the total iron ore production.

With the exhaustion of the Cleveland and some other deposits which have been important in the past, expansion of iron ore capacity to help meet the increasing requirements of the iron and steel industry involves mainly the Northampton Sand bed and to a lesser extent the Frodingham Ore Bed. Although there are many factors that make steel produced locally from domestic ores competitive with steel made from high-grade imported ores, in spite of the low average grade of domestic output, there is a limit to the relative quantity which can be economically consumed in the industry and the rate at which the ores can be mined with consideration for conservation of resources and the welfare of the mining districts. While the Frodingham ore averages only about 20 percent iron, it is calcareous and can be used in blending to replace limestone flux in the furnace charge. On the other hand the Northampton sand ore contains about 31 percent iron, but is generally silicious and requires blending with limestone or the lower grade calcareous ores for fluxing. However, since these ores are basically carbonates, their iron content is increased by calcination or sintering and they make a self-fluxing sinter when properly blended. The marlstones, and some Frodingham ironstone therefore have been used extensively in sinter plants for blending with imported high-grade silicious ores.

The Iron and Steel Board has concluded [2] that consumption of 32 million tons (32.5 million metric tons equivalent) of domestic ore could be expected in 1970 based on capacity operation of the iron and steel industry, and that this would represent the maximum desirable rate of extraction with respect to the presently known reserves, quantitative estimates of which were reported as follows:

Area	Reserve (million metric tons)	
	Proved and probable	Possible
Frodingham	860	530
Northampton Sand:		
North of the River Welland	830	145
South of the River Welland	740	115
Oxfordshire and Southwest:		
Northampton Marlstone	220	110
South Lincolnshire and Leicester Marlstone	1	

[2] Iron and Steel Board, Development in the Iron and Steel Industry, Special Report, 1961, p. 74.

Digitized by Google

The larger part of the iron ore mining was conducted by the iron and steel companies which consumed the ore, the principal of which were (1) Stewarts and Lloyds with main operations concentrated in the Northampton Sand bed around Corby, south of the Welland, and other operations at Thistleton north of the Welland and in the Oxfordshire field, and (2) the United Steel Companies with operations in the Northampton sand at Colsterworth north of the Welland, in the Frodingham ore bed near Scunthorpe, and in the Cumberland hematite field near Workington. GKN Steel Company Ltd., Richard Thomas and Baldwins Ltd., and some foundry iron producers were also producers of iron ore.

Imports of iron ore during 1963 increased by 11 percent over imports in 1962 to 14.55 million tons of which 4.7 million tons were derived from Sweden, 2.4 million from Canada, and about 1 million tons each from Venezuela and Liberia. No exports of iron ore were reported.

Scrap.—During 1963, as in 1961 and 1962, domestic scrap was available in excess of steel industry requirements. Imports were insignificant, amounting to less than 5,000 tons. Under relaxation of restrictions on the export of ferrous scrap, 1.08 million tons were exported, of which 55 percent went to countries of the European Coal and Steel Community (ECSC), 17 percent to Japan, and 14 percent to Spain. These exports compared with 1.1 million tons in 1962 and 31,000 tons in 1961 when the relaxation took effect. With the tightening of supplies at the end of 1963, however, the Government was requested to reimpose the restrictions. They were to become effective in April 1964; under these restrictions, the only grades of scrap which can be exported are compressed baled iron and steel scrap, turnings and borings, not exceeding an f.o.b. value of £25 per long ton—equivalent to US$71 per metric ton. Consumption of scrap increased by 8.3 percent partially because of the overall increase in crude steel production, and partially because of the increase in the ratio of scrap to pig iron consumed in steelmaking, the latter a result of the increase in output of electric steel, which is made almost entirely from scrap.

Pig Iron.—Production increased by about 6.6 percent over that of 1962 but remained 7.4 percent below the 1960 output. Imports amounted to 201,000 tons, still less than 1 percent of the supply. Consumption in steelworks increased by about 10 percent to 13.5 million tons, while that in iron works and foundries showed only a slight increase over 1962 consumption.

Steel.—The output of 22.88 million tons of crude steel in 1963, while considerably short of the record 24.69 million tons produced in 1960, represented a substantial recovery from the recession which started in 1961 and continued into 1963. Actually, production during the fourth quarter approached the rate for the similar period of 1960, with indications for a record output of both pig iron and crude steel during 1964. Notable was the increase in the production of steel by the oxygen processes (basic bessemer, LD, LD–AC, Rotor and Kaldo) which represented 12.6 percent of the total output for an increase of more than 50 percent, and of steel by the electric processes which represented 9.2 percent of the total, for an increase of more than 40 percent. These high tonnages reflect the changing pattern of steelmaking and were made possible by the commissioning of new facilities under the Iron and Steel Industry Development Program. The output of finished steel showed a parallel trend with a record production of steel sheets, also made possible by recently completed facilities.

There was a general increase in the imports of all classes of iron and steel, the total increment amounting to about 527,000 tons, or 48 percent more than in 1962. Exports declined in most classes, but the increase in tonnage of flat rolled products exported (22 percent over that of 1962) more than offset the decreases.

New Developments in the Industry.—Postwar projects costing more than US$280,000 each carried out under the supervision of the Iron and Steel Board or its predecessors, and completed through 1963 represented a total capital investment of about US$4,250 million, and resulted in the expansion of pig iron capacity to about 22 million tons and crude steel capacity to more than 29 million tons. At the same time, old but still economic plants and equipment were modernized,

Digitized by Google

and obsolete plants representing a capacity of more than 6 million tons of pig iron and 7 million tons of crude steel were replaced or withdrawn. However, there was still in operation at the beginning of 1964 somewhat more than 1 million tons of obsolescent steelmaking capacity.

TABLE 9.—Iron and steel trade in 1963

[1] Less than 500 tons.
[2] Included with "other countries."

At the end of 1963 the British iron and steel industry consisted of some 350 companies with total employment of about 475,000 (including iron mines and quarries). Twenty-three of these were major companies which together with their subsidiaries accounted for about 96 percent of the pig iron and 94 percent of the crude steel produced in 1960, and which should control about the same proportions of the production potential scheduled for 1965.

The location of most of the iron and steel plants was determined primarily by the availability of coal, iron ore, scrap, labor, and markets; the latter also has determined the nature of the products. However, depletion of many local coal and iron ore deposits, changes in regional economy, and the pressures of competition from abroad have reduced or otherwise altered the relative importance of these factors, and the new works have been projected with consideration for national requirements as well as local. The result has been a broadening of the variety of products created in each district, a general expansion of capacity in all categories, and a substantial relative increase in wide strip and sheet mill capacity.

[1] Includes blast furnace ferroalloys.
[2] Data are not available.
[3] Includes about one million tons of obsolescent capacity.

Digitized by Google

Noteworthy among the technological developments were the adoption of high top pressures and oil injection in blast furnace practice, application of the oxygen or oxygen-steam blast to open hearth and bessemer steel furnaces, the replacement of open hearth capacity with electric melting facilities, adoption of the new oxygen steelmaking processes (LD, LD–AC, Kaldo, and Rotor), in steelworks, the installation of vacuum degassing and continuous casting equipment, the installation of gas cleaning equipment to inhibit air pollution, and the installation of automatic control systems.

General Data and New Developments in Specific Areas and Plants.—The iron and steel industry of Scotland (Lanarkshire) is based on local coal and scrap and imported iron ores. The principal products are heavy plate and sections for the shipbuilding and heavy engineering industries, and light plate, sheets and tubes; the district accounted for 18 percent of the 1960 output of heavy plates and sections. Colvilles' works completed in 1963, at Ravenscraig, near Motherwell, represents both an expansion and diversification. It is a completely new iron and steel works which produces open-hearth and LD steel for a 60-inch-wide hot strip mill and an associated cold reduction mill at Gartcosh 8 miles from Motherwell. The facility includes two blast furnaces, two 100-ton LD converters, and one 250-ton open-hearth furnace integrated with a slabbing and blooming mill and the hot strip mill. It is expected to produce 900,000 tons of pig iron, 1,260,000 tons of ingot steel, 500,000 tons of sheets, and 175,000 tons of light plates annually.

The industry of the Northeast coast district, site of the works of three major iron and steel companies, is based on local coal and scrap and imported iron ores. The district accounted for 41 percent of the 1960 output of heavy plates and sections for the shipbuilding and engineering construction industries and 11 percent of the 1960 output of light rolled products.

The Consett Iron Co., Ltd., with works at Consett, Durham, had completed, prior to 1963, an iron and steel works with an open-hearth melting shop to supply steel to an integrated 4-high 11-foot plate mill, designed to replace older mills. Nearly complete at yearend was an additional oxygen steelworks, consisting of two 100-ton LD and two 100-ton Kaldo converters, and designed to supply steel to a continuous strip and bar mill which was also under construction.

The Dorman Long (Steel), Ltd., with works on the east side of the River Tees near Middlesborough, North Riding, Yorkshire, completed a new slabbing and blooming mill at Lackenby in 1963. This completion was one of the last stages of a major modernization and expansion program undertaken by the company soon after World War II. Among the objects of the project were concentration of ore handling and iron making at Cleveland and the development at Lackenby of steelmaking and rolling mill facilities which could be more or less integrated with the nearby Cleveland and Redcar works. Completed at yearend were three new blast furnaces, a blooming mill and medium section mill at Cleveland, and an open-hearth melting shop with a capacity of about 900,000 ingot tons annually, rolling mills including a billet mill, a universal beam and heavy section mill, a rod, bar and narrow strip mill, and a slabbing and blooming mill at Lack-

Digitized by Google

enby. Still under construction were a wire rod mill, universal plate mill, and cold rolling equipment. The expected crude steel capacity of the combined works was reported as 2,600,000 tons annually.

Recent developments in the South Durham Steel and Iron Co., Ltd., works at Cargo Fleet, West Hartlepool, and Stockton-on-Tees, Durham, for the most part were commissioned prior to 1963. These included additional capacity at the Cargo Fleet and the West Hartlepool North Works for iron and steel making and the rolling of light, medium, and heavy plate, heavy sections, and universal beams. A new integrated works (South Works) designed for the production of heavy steel plate was constructed at Greatham, West Hartlepool. The works include coke ovens, a blast furnace, open-hearth melting shop, a slabbing mill, and a 2-stand 4-high 12½-foot plate mill. Reported steel capacity was 830,000 ingot tons annually.

The three major iron and steel works of the Lincolnshire district located at Scunthorpe are based on Yorkshire coal, regional scrap, and local (Frodingham and Northampton Sand) iron ores. The principal products are plate, heavy and light sections, and semis for finishing elsewhere. The United Steel Companies' Appleby-Frodingham branch developed the so-called Ajax equipment designed for the conversion of older open-hearth furnaces to utilize oxygen injection for increased productivity. Through 1963, six furnaces had been converted to the Ajax design and one was in progress. Replacements and additions increased capacity for the production of plates, heavy sections, and universal beams. New installations included a billet mill, a continuous rod and bar mill (capacity 300,000 to 350,000 tons annually) and a continuous casting plant for the casting of 9-inch-square blooms (capacity 250,000 tons annually).

Lysaght's Scunthorpe Works of the GKN Steel Co., Ltd., produces billets, blooms, sheet bar, and wire rod. A major expansion project completed in 1960 included new ore preparation, sinter, and blast furnace installations and additional billet and rod mill capacity. Partially completed in 1963 was a further expansion project scheduled for completion during 1964 including ironstone mine development, ore preparation, sinter plant, an oxygen steel melting shop comprising two 50-ton LDAC converters and a mixer. This plant, when completed, should increase Lysaght's crude steel capacity to more than 1 million ingot tons annually.

Richard Thomas and Baldwins' Redbourn Works produce billets, sheet bars, and slabs. The major modernization and expansion project, completed in 1962, included enlarging and relining of three blast furnaces, new ore preparation and sinter plants, the installation of two Rotor (oxygen process) furnaces, and the replacement of cogging and billet mills by new units including an 8-stand continuous-billet mill. Under construction at yearend was a new hot scarfing machine for billets. These projects bring the capacity of the Redbourn Works to 690,000 tons of ingot steel and 600,000 tons of billets annually.

The Northwest coal (Cumberland and north Lancashire) area's Workington Iron Company branch of United Steel Companies at Workington, Cumberland, comprises Britain's only major acid Bessemer steelworks. Originally based on local coal and scrap iron and the low-phosphorus hemetite ores of the Cumberland fields, the works

Digitized by Google

is now dependent to a large extent on imported ores. The products are predominantly steel rails and railway track material. Modernization and replacement of rolling mill equipment and generating plant was completed in 1962.

The Barrow Iron Works, Barrow-in-Furness, Lancashire, one of the last companies to be denationalized, was acquired in January 1963 by the Millom Hematite Ore and Iron Co. of Millom, Cumberland, which at the same time announced the intention of closing the works because the capacity is no longer needed. The Millom Co. completed a program of replacement and expansion at its Millom works which was initiated while the works was still under nationalized control.

The Barrow Steel Works, Ltd., Barrow-in-Furness, Cumberland, is owned by the United Steel Companies, Ltd., and is used as a research establishment for continuous casting. The works has a capacity of 50,000 tons of ingot steel annually and consists of one 7-ton electric arc furnace, one 20-ton electric arc furnace supplying steel to three twin-strand continuous casting machines and integrated rolling mills to produce billets, blooms, slabs, bars, sections, hoop, and strip.

At the beginning of 1963 the Sheffield district (Yorkshire other than North Riding) had one blast furnace plant, which utilized domestic ore from Lincolnshire and Northhamptonshire, and 43 steelworks and foundries with a total of 243 steel furnaces including 23 acid open-hearth, 37 basic open-hearth, 4 Tropenas, 57 electric arc and 122 electric-induction, dependent mainly on local scrap from the manufacturing industries and pig iron from other districts. During the peak year of 1960 the district accounted for 12.6 percent of the total crude steel output and 68 percent of the 1.65 million tons of alloy steel produced.

The Steel Peech and Tozer branch, United Steel Companies, Ltd., in the Sheffield district, had completed and put into operation at Templeborough 3 new 110-ton electric arc furnaces as part of a major project involving the replacement of 21 existing open-hearth furnaces at their Templeborough and Rotherham Works by a new electric melting shop at Templeborough. When completed, the new shop will consist of six 110-ton electric arc furnaces with vacuum casting facilities designed to produce 1,350,000 ingot tons of crude steel annually and is expected to be the world's largest electric melting shop. The project also included modernization of the bar mill and a new 4-stand cold reduction mill to operate in conjunction with a medium width hot strip mill at Brinsworth completed in 1960. In addition to billets, bars, sections, and strip, this company is a leading producer of railway rolling stock.

The English Steel Corp. completed in 1963, on a new site at Tinsley Park, Sheffield, a new melting shop and rolling mill consisting of two 100-ton electric arc furnaces with vacuum degassing equipment, a 42-inch blooming mill, two 32-inch billet mills, an 18-inch roughing bar mill and 18-inch, 14-inch, and 11-inch finishing mills. This facility will produce billets and bars of alloy and special carbon steel and will permit the closing of the obsolete works in Sheffield. In 1962 the company completed a vacuum melting plant at their River Don Works in Sheffield and a ladle degassing unit at their Openshaw Works in Manchester.

Digitized by Google

The Park Gate Iron and Steel Co., Ltd., subsidiary of Tube Investments, Ltd., had scheduled for completion in 1964 at Rotherham in the Sheffield area, a new steelworks comprising two 75-ton Kaldo oxygen converters, a 75-ton electric arc furnace, a rotary steel casting plant, a 42-inch blooming mill, a continuous billet mill, and a continuous narrow hot strip mill. This works was in addition to the existing works at Park Gate comprising 10 oxygen-equipped open-hearth furnaces which supply mills for the production of bars and sections; the Rotherham steelworks was designed to raise the output of crude steel by 375,000 ingot tons to 800,000 ingot tons annually and to provide the Tube Investments group with additional hot-rolled strip for tube-making as well as to increase its output of alloy and high-grade steel products.

Samuel Fox and Son, subsidiary of United Steel Companies, completed additional electric arc melting, billet, bar rod and plate production facilities to increase the output and range of these products at its Stocksbridge Works in Sheffield.

Thomas Firth and John Brown, Ltd., completed replacements and additions at their Atlas Works in Sheffield, including new electric arc furnaces, a vacuum melting plant, heat treatment facilities, and forging presses designed to increase capacity for the production of semis, plates, sheets, and medium sized forgings of carbon, alloy, tool, and special steels. Work continued on a ring rolling plant scheduled for completion in 1964. Output in 1960 amounted to about 180,000 tons of ingot steel.

Hadfields, Ltd., continued a major program of repairs and replacements at their East Hecla Works at Sheffield, including a vacuum melting plant installed in 1962 and replacements in the forging shop, still in progress at the end of 1963. Other facilities at East Hecla include basic open-hearth, acid Tropenas, electric arc, high frequency and vacuum furnaces, cogging billet and bar mills, heavy and light forges, and steel foundries, including a precision foundry. Output in 1960 amounted to approximately 130,000 tons of ingot alloy steel and 85,000 tons of billets, bars, castings, and forgings.

Steelworks in the Lancashire district (except its northern part), including Denbighshire, Flintshire, and Cheshire, are based on local or regional scrap, and imported iron ore. Principal products are billets, sections, rods plates, sheets, and tubes of alloy and nonalloy steel.

The Lancashire Steel Manufacturing Co., Ltd., had completed a major expansion project in 1962 at their Irlam Works including additional ore preparation, sinter plant, blast furnace, open-hearth steelmaking capacity, cogging, billet, rod, and bar mills to increase steel capacity to approximately 875,000 ingot tons and wire rod capacity to about 500,000 tons. Ladle degassing equipment was installed during 1963.

Scheduled for completion in 1964 at the Brymbo Works of the GKN Steel Co., Ltd., near Wrexham, Denbighshire, was a new inspection unit for its oxygen-electric alloy steelworks commissioned in 1959. Among unique features at this works is the oxygen prerefining unit of the company's own design that takes hot metal from the blast furnace and prerefines it for direct use in the electric arc furnaces, permit-

Digitized by Google

ting a high ratio of hot metal to scrap. The works comprises a blast furnace, oxygen prerefining vessel, three 20-ton electric arc furnaces, three 40-ton electric induction furnaces, a blooming mill, and billet mills and was designed to replace an existing open-hearth steelworks. Reported capacity was 75,000 tons of pig iron and 275,000 tons of crude steel, and 180,000 tons of alloy steel billets annually.

A modernization and expansion program started in 1954 and completed in 1961–62 at the John Summers and Sons, Ltd., Works in Shotton, Cheshire, included additions to ore preparation, sinter, blast furnace and open-hearth steelplants, improvements to the existing slabbing and hot strip mill, additional reheating furnaces, a third drum coiler and a universal roughing stand, and a 56-inch cold reduction mill. The new facilities were designed to increase sheet processing capacity to about 1,650,000 tons annually. Principal products were heavy and medium plates, hot rolled strip, hot rolled and cold reduced sheets including zinc coated, galvanized, and plastic coated sheets.

The principal iron and steel works of the Northamptonshire, Derbyshire, Nottinghamshire, and Leicestershire area is the Stewarts and Lloyds, Ltd., integrated works at Corby. It is based on regional coal and scrap and the relatively high phosphorous Northampton Sand Ironstone, and it produces strip, pipes, and tubes from basic bessemer steel. With works also in other districts, this company is the United Kingdom's leading producer of pipe and tube. A major modernization and development program completed in 1959 resulted in the modification of the five existing basic bessemer furnaces for oxygen or oxygen-steam blowing, the installation of a tonnage oxygen plant, and the modernization of the blooming and heavy rolling mills.

A further expansion project included the installation of an experimental LDAC oxygen converter of 100 tons capacity in 1961, an increase in the capacity for rolling billets and strip completed in 1963, and provides for an increase in crude steel capacity to 1,550,000 ingot tons annually. On the basis of results obtained from the experimental LDAC unit, work was in progress on a new LDAC steelmaking shop scheduled for completion in 1965, which will replace the existing basic bessemer shop and provide steel for the expanded works. An additional blast furnace was also foreseen in the project, but construction was temporarily deferred.

In the Staffordshire and Worcestershire district, the Shelton Iron and Steel, Ltd., a subsidiary of John Summers and Sons, Ltd., had in progress in 1963 and scheduled for completion in mid-1964 a major project including a completely new oxygen steelworks designed to replace the basic open-hearth melting shop at Stoke-on-Trent, Staffordshire. The works will be integrated with the existing blast furnace plant and comprises a 1,000-ton mixer, two 55-ton Kaldo converters, four continuous casting machines capable of casting blooms to a maximum of 24 inches by 17 inches and slabs to a maximum of 42 inches by 18 inches, and a structural and universal beam mill. Steelmaking capacity will be increased to about 350,000 ingot tons annually.

Patent Shaft Steel Works, Ltd., at its Wednesbury Works, Staffordshire, had completed new open-hearth steelmaking facilities, a new slabbing-blooming-billet mill, and a new heavy plate mill in 1959.

Round Oak Steel Works, Brierly Hill, Staffordshire, completed

Digitized by Google

in 1959 and 1961, two 65-ton electric arc furnaces and additional capacity for alloy tube rounds; in 1963 a pilot plant for continuous casting supplied by a 5-ton electric arc furnace was completed.

Stewarts and Lloyds, Ltd., Bilston Works completed improvements to their blast furnaces and open-hearth melting shop in 1958, and replacement of blooming, bar, and billet mills in 1961.

Operations in South Wales and Monmouthshire are based on local coal and scrap and imported iron ore. A large part of the country's sheet and all of the tinplate production is centered here. In 1960 the district accounted for 62 percent of the country's production of sheet, 14 percent of the light rolled products, and 7 percent of the heavy plates and sections.

In 1963 the Guest Keen Iron and Steel Works, at Cardiff, Glamorganshire (South Wales), completed a major modernization project which included equipment permitting the simultaneous operation of four blast furnaces, a new ore preparation and sinter plant, oxygen injection in the open-hearth steel furnaces, and additional roughing facilities ahead of the existing continuous billet mill. Crude steel capacity was raised to over 1 million ingot tons. The principal products are billets and heavy sections.

The Briton Ferry Steel Co., Ltd., Briton Ferry, Glamorganshire, commissioned a new 100-ton open-hearth furnace in 1959 which raised crude steel capacity to about 300,000 ingot tons annually. The principal product is billets.

The Steel Company of Wales' Margam and Abbey Works at Port Talbot, Glamorganshire, which were designed to improve the United Kingdom's supply of steel sheet and tin plate, represented the British iron and steel industry's largest postwar expansion project. The works consist of rail and dock terminals with coal and ore handling facilities; coking plant; ore preparation, sinter and blast furnace plants; open hearth and VLN (very low nitrogen) oxygen-steam converter steelmaking shops; and a continuous casting plant integrated with a universal slabbing mill, an 80-inch hot strip mill, and two cold reduction mills—one 3 stand, 80 inches wide and one 4 stand, 56 inches wide. As a part of the major project, tin plate mills were constructed at Trostre and Velindre, 22 and 15 miles, respectively, from Port Talbot. Works at Orb near Newport, Monmouthshire, were acquired and developed for the production of electrical sheet. New installations at Orb included a 48-inch cold reduction and a Sendzimer 14-inch cold reduction mill. The improvements completed in 1963 raised crude steel capacity at Port Talbot to about 3,650,000 ingot tons annually.

Included in the project were provisions for the processing of slabs from the Abbey Works into hot strip at the Spencer Works of Richard Thomas and Baldwins and returning the strip to the Steel Company of Wales for further processing.

Modernization of the Richard Thomas and Baldwins, Ltd., Ebbw Vale Works, Monmouthshire, included replacements and additions to blast furnace, steelmaking, rolling and tinning facilities, the conversion of the basic bessemer converters for oxygen-steam blowing, and the replacement in 1960 of one bessemer converter by an LD oxygen converter for experimental purposes. On the basis of results obtained, a new project was initiated in 1962 to convert the bessemer

Digitized by Google

steelmaking shop to LDAC practice. The conversion involved two remaining furnaces with fume cleaning equipment, one of which was commissioned in 1963. The other was scheduled for completion in 1964. The principal products at Ebbw Vale were plate, sheets, and tinplate.

The Spencer Works at Llanwern near Newport, Monmouthshire, is a new fully integrated iron and steel works designed to produce hot strip and cold reduced sheet from imported ore and local scrap. The works, commissioned in October 1962, includes coke ovens, ore preparation and sinter plants; two blast furnaces with 30-foot hearth diameter; an oxygen steelmaking shop with three LD converters; a universal slabbing mill; a 68-inch continuous hot strip mill; and a 66-inch continuous cold reduction mill. Initial crude steel capacity was rated at about 1,400,000 ingot tons, with provisions on the site for future expansion.

Lead and Zinc.—*Production and Trade.*—The production of refined lead from ores, concentrates and scrap rose 7 percent over that of 1962. Imports of concentrates and scrap declined somewhat, while those of lead bullion (58,936 tons) and refined lead (124,378 tons) combined were about equal to the imports of these commodities in 1961 and 1962. Australia and Canada continued to be the principal sources of supply; domestic ore and concentrate production has been limited to that derived as a byproduct of barite and fluorspar since the closure of the Greenside lead mine in the Lake district in Westmoreland in 1959. This was the last property in the United Kingdom to be operated primarily as a lead mine. Exports of refined lead in 1963 increased by nearly 12 percent to 40,065 tons, while exports of alloys and wrought metal remained about the same. West Germany with 28,662 tons was the leading customer, followed by the United States with 4,021 tons. Consumption of unwrought primary, secondary, and scrap lead rose to more than 393,000 tons and was believed to be higher than in any peacetime year.

The 1963 output of slab zinc was also a record high, continuing a trend toward increasing zinc metal production that received an added impetus with the commissioning in 1960 of a new standard size Imperial Smelting Furnace at the Swansea Vale Works of the Imperial Smelting Corp. This was the first standard size furnace using the Imperial Smelting Process developed at Avonmouth for the simultaneous recovery of slab zinc and lead bullion with associated metals from mixed concentrates and residues. The increased output since 1960 was due largely to improved efficiency. Imports of 104,729 tons of zinc in concentrates and 162,760 tons of slab zinc were each more than 10 percent above the level of imports in 1962, while exports of 10,160 tons of slab zinc and 4,400 tons of semimanufactures represented a modest decrease in total zinc exported. Consumption of zinc in all forms showed a substantial increase (7 percent) over that of 1962 but still remained below the high level of 1960.

Domestic Mines, Resources, and Processing Facilities.—Mining of lead and zinc ore in Great Britain historically predates the Roman occupation of that island and has included periods of more or less continuous mining operations which have extended over centuries. It is doubtful whether the remaining known reserves of lead and zinc

758-002—65——52

Digitized by Google

ores are sufficient in quantity and grade either to play an important role in the mineral economy of the country except in the absence of other sources of supply, or to maintain an economic mining operation except under very favorable market conditions. However, the country's extensive mineralized areas and zones which have been important sources of past lead and zinc ore production, some of which were of considerable importance from a world standpoint, may still contain important deposits susceptible to discovery by conventional or improved modern methods of prospecting and economic extraction. Most productive of lead and zinc ores was the Northern Pennine orefield which is credited with a total production of about 4 million tons of lead concentrates (70 to 80 percent lead) and 267,000 tons of zinc concentrates (40 to 55 percent zinc) as well as large tonnages of fluorspar, barite and witherite.

Other favorable areas with substantial past production of nonferrous metals are the Leadhills Wanlockhead mining district in Scotland, the Lake district mining field in Cumberland and Westmoreland, the Derbyshire orefield, and mineralized areas on Anglesey (copper) and in north and central Wales.

Some limited exploration and development projects have been undertaken and others have been under consideration to resume development and mining in certain of the traditional mining districts, but the depressed state of the lead and zinc mining industries during 1954–63 was no doubt responsible for delaying further action on these projects.

The principal producers of refined lead, lead alloys, and slab zinc were as follows:

Company	Type of works	Location	Annual capacity where available
Associated Lead Manufacturers, Ltd.	Smelters and manufacturing plants.	Newcastle, Chester, Hull, and London.	Aggregate capacity 70,000 tons refined lead.
Britannia Lead Co., Ltd.	Lead-silver refinery	Northfleet, Kent	91,500 tons refined lead.
British Lead Mills, Ltd.	Refinery for scrap and residues.	Welwyn Garden City, Hertfordshire.	
H. J. Enthoven and Sons, Ltd.	Smelters, refineries and manufacturing plants.	Rotherhithe, London and Darley Dale, Derbyshire.	(16,000 tons refined lead). (30,000 tons refined lead).
Imperial Smelting Corp., Ltd.	Lead-zinc smelters	Avonmouth, Gloucestershire and Swansea, South Wales.	100,000 tons slab zinc.
	Other works	Seaton Carew and Newport, Monmouthshire; Bloxwich, Staffordshire; Widnes, Lancashire; Burry Port, South Wales.	
Lead and Alloys, Ltd.	Smelters and refineries	Abbey Wood, London; and Thorpe, near Wakefield, Yorkshire.	Aggregate capacity 10,000 tons refined lead.
Capper Pass and Son, Ltd.	Smelters and refineries	Bristol, Gloucestershire and North Ferriby, Yorkshire.	
Platt Metals, Ltd.	Smelter and refinery	Enfield, Middlesex	
Rhondda Metal Co., Ltd.	Refinery	Porth, South Wales.	
Sheffield Smelting Co., Ltd.	Nonferrous rare and precious metal smelter and refinery.	Sheffield	
	Rolling mills and machine shops.	Sheffield and Birmingham.	

Nickel.—Estimates on production and consumption of nickel in 1963 indicate little change from the output of 38,300 tons and consumption

Digitized by Google

of 25,100 tons recorded for 1962. Imports in 1963 consisted of matte and speiss 62,620 tons (up 15 percent); scrap 2,533 tons (up 6 percent); unwrought nickel and nickel alloys (down 2 percent); and semimanufactures 3,141 tons (down 26 percent). Exports in 1963 consisted of unwrought nickel and alloys 23,971 tons (up 16 percent) and semimanufactures 6,447 tons (up 14 percent).

The Mond Nickel Co., Ltd., a subsidiary of the International Nickel Co., with a nickel refinery at Clydach, South Wales, and a precious-metals refinery at Bashley Road, London, is the country's only producer of primary refined nickel; its subsidiary company, Henry Wiggin & Co., Ltd., with plants at Glasgow, Birmingham, and Hereford is a major producer of alloys.

Tin.—The output of primary and secondary tin in 1963 continued a more or less steady decline from the peak production of 34,500 tons in 1957. The tin content of domestic ore mined, however, showed little variation from the average annual output since 1957.

Imports in 1963 consisted of ores and concentrates 16,205 tons (down 7 percent); and refined tin 7,927 tons (down 14 percent). Exports of refined tin declined by 8 percent to 8,675 tons of which 219 tons were re-exports, while exports of solder increased by 30 percent to 2,033 tons.

South Crofty, Ltd., with operations at Redruth in Cornwall, and the Geevor Tin Mines, Ltd., at Pendeen in Cornwall accounted for the entire output of tin ores in the proportion of approximately 56 percent and 44 percent, respectively. Both of these mines appear to have adequate reserves and favorable development possibilities in adjacent areas including possible extensions under the sea to maintain operations at the present rate for a number of years under reasonably favorable conditions. Other possibilities associated with old abandoned workings or undiscovered extensions of the granite batholith are recognized. Tin smelting capacity in the United Kingdom was reported as 65,000 tons of refined tin annually. The principal producers were—Consolidated Tin Smelters, Ltd., a subsidiary of Williams, Harvey & Co., Ltd., with works at Bootle, Lancashire, which produced refined tin; Capper Pass & Son, Ltd., with works at Bristol and North Ferriby, Yorkshire, which produced tin, tin base alloys, solder, other nonferrous metals and alloys; and Batchelor, Robinson & Co., Ltd., with works at West Hartlepool, Durham, and Llanelly, Monmouthshire, which produced tin and solder.

NONMETALS

Barite and Witherite.—The drop in output of barite in 1963 was due principally to the closure of the Silverband Mine of Laport Industries, Ltd., at Dunfell, Westmoreland, and of the Gasswater Mine of Anglo Austral Mines, Ltd., at Cronberry, Ayrshire. Although, some new production may be expected as a byproduct from expanded fluorspar production facilities, the overall reduction in output was in accordance with barite market requirements in the United Kingdom. Imports were not affected because the requirement of certain industries for barite of certain qualities, including white barite for the paint industry, cannot be met from domestic crude barite. Imports in 1963 amounted to 28,448 tons, a rise of about 2 percent over imports in 1962.

Digitized by Google

The Settlingstones Mine of Settlingstones Mines, Ltd., at Fourstones, Hexham, Northumberland continued to be the country's only producer of witherite. The Muirshiels Mine of Muirshiels Barytes, Ltd., at Lockwinnock, Renfrewshire, was the principal producer of barite. The remaining output of barite was produced as a coproduct or by-product of fluorspar mining, or the processing of old lead-zinc dumps.

China Clay.—The United Kingdom continued to be the world's second largest producer and the world's largest exporter of china clay. While production in 1963 rose slightly to 1.73 million tons, exports increased nearly 14 percent to 1.271 million tons, reflecting the fruition of a program of progressive modernization of quarry operations which took place in the industry during 1959–63.

The entire output of china clay came from quarries in Cornwall and Devon, in the relative proportion of about 90 percent and 10 percent, respectively, where it occurs as an in-place hydrothermal alteration product in the granite batholith whose principal outcrops are identified as Dartmoor, Bodmin Moor, the St. Austel Mass, Carn Menellis, and Lands End Mass. The copper-tin-tungsten deposits of Cornwall and Devon are also associated with this batholith.

The principal producing company is English China Clays, Ltd., with operations in both Devon and Cornwall. This company and its subsidiaries are also principal producers of potters clay, which occurs in Devon, and of a variety of construction materials.

Other producers of china clay are S. W. Berk & Co., Ltd., Goonvean, Ltd., and certain paper and cement manufacturers who own china clay pits.

Fluorspar.—Production of fluorspar declined a further 6 percent in 1963, continuing a downward trend from the 1960 high, due partially to the depressed state of the steel industry which did not recover in time to affect fluorspar production, and partially to diminished demand in the chemical industries. Districts in Durham and North Derbyshire, formerly important for lead production, continued as the principal sources of fluorspar supply. Blanchland Fluor Mines, Ltd., a subsidiary of Colvilles, installed a heavy media seperation plant in 1963 at their Whiteheaps Mine at Blanchland, North Durham, to operate in conjunction with their flotation plant. The combined capacity will be 15,000 tons of acid-grade fluorspar and 25,000 tons of metallurgical-grade fluorspar anually. Among other operating companies in North Durham were Beckermet Mining Co., subsidiary of United Steel Companies, with a gravity-flotation plant at the Blackdene mine near Wearhead; Fluorspar, Ltd., with a flotation plant at the Stanhopeburn Mine near Stanhope; and the Weardale Lead Co., Ltd., with a gravity-flotation plant including heavy media separation at the Stotsfield Burn Mine near Rookhope.

Glebe Mines, Ltd., subsidiary of Laporte Industries, Ltd., completed in 1962 additions to the Glebe and Cupola mills near Eyam, North Derbyshire, bringing the combined capacity of the group to 45,000 tons acid-grade fluorspar, 18,000 tons of barite, and 2,000 tons of lead concentrates annually.

Gypsum and Anhydrite.—The United Kingdom's 1963 production of gypsum and anhydrite continued a trend which showed an average annual increase of more than 4.5 percent in the production of gypsum

Digitized by Google

and anhydrite during 1959–63. Official figures for 1963 were not yet available, but foreign trade during the preceding years has played only a small role in the United Kingdom gypsum supply position. During 1959–62 imports including alabaster averaged about 133,400 tons annually, while exports averaged only 10,300 tons. Apparent consumption in 1962 amounted to about 4.190 million tons of gypsum and anhydrite of which about 862,000 tons was anhydrite consumed in the manufacture of sulfuric acid.

Cumberland, Durham, Sussex, and Nottinghamshire continued to be the principal sources of supply. During recent years the most important operations have been modernized and brought to a high state of efficiency. The important producers include:

Company	Mines	Town or city	County
Imperial Chemical Industries (fertilizers and synthetic products), Ltd.	Billingham	Billingham	Durham.
Carlisle Plaster and Cement Co., Ltd.	Cocklakes	Carlisle	Cumberland.
	Long Meg	Langworthby	Do.
Solway Chemicals, Ltd	Sandwith	Whitehaven	Do.
Thomas McGhie & Sons	Birkshead	Long Marton	Do.
	New Stamphill	Kirby Thore	Do.
British Plaster Board, Ltd		Bunny	Nottinghamshire.
		East Lake	Do.
Gotham Co., Ltd		Cropwell Bishop	Do.
		Gotham	Do.
		Thrumpton	Do.
Gypsum Mines, Ltd	Kingston on-Soar		Do.
	Subwealden	Mountfield	Sussex.
J. C. Stratton & Co	Faulds	Hanbury	South Staffordshire.

Salt.—Increased demand for rock salt to keep British roads ice free was largely responsible for the nearly 58-percent increase in salt output in 1963. Through expansion and further mechanization of underground facilities at the United Kingdom's only rock salt mine, the Meadowbank Mine of Imperial Chemical Industries at Winsford, Cheshire, capacity was to be increased to 1 million tons of rock salt annually by 1964.

Production of evaporated salt increased by about 8.5 percent to 1.389 million tons, while estimates of brine output for purposes other than saltmaking indicated little change.

Exports of evaporated salt rose 8.5 percent to 253,200 tons, while exports of other salt rose by 30 percent to 93,500 tons.

The principal producer of salt in the United Kingdom was Imperial Chemical Industries, Ltd., salt works at Winsford and Weston Point, Cheshire; Stoke Prior, Worcestershire, Port Clarence, Staffordshire; and Carrickfergus, Northern Ireland.

It was reported that a geophysical survey conducted by the Department of Scientific Research in Northern Ireland disclosed the presence of extensive salt deposits at Larne in Antrim County.

Strontium Minerals (Celestite).—In the absence of official output and trade figures for 1963 it is presumed that production continued at about the same rate as in 1962. Exports averaged about 4,400 tons annually during 1959–62. Production came entirely from the vicinity of Yate, near Bristol in Gloucestershire, where the mineral occurs as

Digitized by Google

lenses and lenticular masses between the bedding planes of Keuper clays.

The Bristol Land & Mineral Co., Ltd., Bristol, is the principal producing company.

MINERAL FUELS

During 1963 the United Kingdom consumed the energy equivalent of 288 million tons of average salable British coal. Coal, however, of which the country has plentiful reserves, provided the raw material for somewhat less than 68 percent of the energy consumed, while petroleum, more than 99 percent of which must be imported, provided about 30 percent of the total; the remainder of total energy was supplied by gases associated with coal production, by nuclear energy plants, and by nuclear and hydroelectricity—a part of which is also imported.

From 1959 through 1963 total consumption of energy in terms of coal equivalent increased about 3.75 percent annually. Although there was a small annual increase in the tonnage of coal consumed, its share in the energy pattern decreased from 75 percent to 68 percent, while petroleum increased its share from 23 percent to 30 percent and supplied about 72 percent of the raw material for the increased energy consumed.

TABLE 11.—Energy balance

(Million tons coal or coal equivalent [1])

Energy source	1959	1960	1961	1962	1963
Coal, direct use	92.8	92.6	85.7	82.6	78.8
Oil, direct use	48.1	55.3	60.4	67.3	74.2
Coke and coke breeze	28.1	32.0	30.1	28.7	29.1
Other solid fuel	1.6	1.4	1.5	1.5	1.6
Coke oven gas	2.1	2.6	2.5	2.1	2.1
Electricity:					
Coal and coke	48.6	53.5	57.2	62.9	69.2
Oil	7.3	9.4	9.8	10.0	8.8
Nuclear electricity	.5	.9	1.1	1.5	2.6
Hydroelectricity	1.5	1.7	2.1	[2] 2.1	[2] 1.8

[1] Conversion factors:
1 ton average salable coal=1 ton coal equivalent.
1 ton oil=1.7 tons coal.
300 therms colliery methane=1 LT coal or 295 therms=1 metric ton coal.
40,000 cubic feet coke oven gas=1 LT coal or 1,115 cubic meters=1 metric ton coal.
1 ton coke breeze=0.9 ton coal.
Coal equivalent of hard coke and gas coke is the coal used at coke ovens less coke, coke breeze, and coke oven gas supplied to consumers, to stocks or for export. Other solid fuels show coal used for production of briquets, etc.

[2] Includes imports.

Coal.—Deep mines under jurisdiction of the National Coal Board (NCB) had on their colliery books an average of about 523,800 wage earners and accounted for 96 percent of all of the coal produced in the United Kingdom during 1963. Employment and output were distributed among the nine National Coal Board Divisions as follows:

Division	Wage earners (thousands)	Output	
		Quantity (thousand metric tons)	Per man-shift (metric tons)
Scottish	55.8	16,832.9	1.395
Northern	33.7	12,173.3	1.596
Durham	75.0	22,389.7	1.333
Yorkshire	112.8	43,850.7	1.821
North Western	36.8	12,116.4	1.536
East Midlands	88.6	47,794.0	2.433
West Midlands	38.4	14,922.7	1.770
South Western	77.5	19,163.7	1.173
South Eastern	5.2	1,635.8	1.435
Total	523.8	190,879.2	1.674

This output was only slightly higher than in 1962 but was derived from fewer operating units with a considerably smaller operating force.

From January 1, 1947, through fiscal year 1963–64 (ending March 31, 1964), capital expenditures approximating US$3,508 million were made by the National Coal Board for the improvement of coal mining and preparation, ancillary plants, and housing for the labor force.

From 1958, when the improvements were beginning to show in operating results, the average increase in output per man-shift for all wage earners employed at NCB mines was slightly more than 5 percent annually and was effected principally through increased mechanization, concentration of productive operations, improvement in mining and cleaning methods, and modernization and replacement of obsolescent equipment.

In its annual report for fiscal year 1963–64 the National Coal Board recommended that efficient coal productive capacity be maintained at a minimum of 200 million tons annually to help meet expanding requirements which would rise from 283 million tons of coal equivalent in 1963 to about 450 million tons of coal equivalent in 1980 if the economy should grow 4 percent annually—as suggested by the National Economic Development Council.

Total	3,978	4,349	4,195	4,144	4,248

[1] Data not available.
[2] Less than 50,000 tons.
[3] Therm equals 100,000 British thermal units (B.t.u.).
[4] Natural gas in 1959 and 1960; LPG in 1961, 1962, and 1963.
[5] All liquefied petroleum gas.

Trade.—Imports of solid fuels were insignificant, amounting to only 66,000 tons in 1963 compared with 78,000 tons in 1962. Exports of coal increased by about 67 percent, while those of briquets and coke increased by 18 percent and 35 percent, respectively. Exports in thousand metric tons, and principal countries or areas of destination are shown below:

Commodity	Total exports 1963	Principal destinations, 1963
Coal	8,002	France 2,119; Netherlands 1,884; other ECSC countries 1,604; Denmark 896; Irish Republic 533; other EFTA countries 436.
Coke and coke breeze	2,019	Norway 627; Denmark 323; ECSC countries 314; Sweden 235; other EFTA countries 178; Venezuela 132; Finland 106.
Briquets	137	ECSC countries 118.

Petroleum.—Although indigenous production of crude petroleum increased by more than 12 percent in 1963, the cessation of shale oil production in Scotland resulted in a net decrease in the output of crude oil. Throughput of crude and process oils and refinery output each increased less than 2 percent, reflecting capacity operations at refineries during 1962 and increasing production as new facilities came on stream in 1963. At the yearend, distillation capacity for crude and process oils had increased by more than 11 percent to about 57.8 mil-

Digitized by Google

lion tons, while expansion projects in progress were designed to add an additional 9.9 million tons capacity by the end of 1964. New proposals for completion by the end of 1967 would increase total capacity to about 89 million metric tons.

Imports of crude and process oils increased by about 4 percent from 53,189 million tons in 1962 to 55,377 million tons in 1963, while imports of refined products increased 17 percent from 15,087 million tons in 1962 to 17,695 million tons in 1963. The principal countries of origin were:

Commodity	Quantity (thousand tons)	Value (million U.S. dollars)
Crude and partly refined oils:		
Kuwait	22,032	403.2
Other Middle East	15,767	310.4
Venezuela	6,078	115.3
Libya	5,902	117.9
Nigeria	2,408	48.2
Other countries	3,190	75.0
Total	55,377	1,070.0
Refinery products:		
Netherlands	2,699	75.1
Other Europe	3,847	102.3
Bahrain, Kuwait, Qatar, and Trucial Oman	2,306	64.8
Other Middle East	1,500	40.2
Netherlands Antilles	1,794	51.4
Trinidad and Tobago	2,450	64.4
Venezuela	2,532	51.7
United States	397	22.8
All other countries	170	6.2
Total	17,695	478.9

Exports and re-exports of crude and partially refined oils increased from 1,007,000 metric tons to 1,444,000 tons, while those of refined products decreased from 9,859,000 tons to 9,791,000 tons. The principal countries of destination were:

Country	Quantity (thousand metric tons)	Value (million U.S. dollars)
Denmark and Faroes	2,032	54.0
Germany, West	1,175	31.0
Ireland	429	15.5
Netherlands	2,314	47.6
Norway	1,143	26.1
Sweden	2,604	60.9
Other countries	1,538	76.7
Total	11,235	311.8

Digitized by Google

Included in the above are crude and partially refined oils (in thousand tons)—West Germany 6, Netherlands 1,420, and others 18.

Developments.—Noteworthy among petroleum developments in the United Kingdom was the introduction to Parliament of the Continental Shelf Bill governing exploration of oil, gas, and coal underlying areas of the North Sea Continental Shelf subject to U.K. jurisdiction under provisions of the Geneva Convention on the High Seas of April 29, 1964. Under this act, rights to the natural resources underlying the seabed outside territorial waters are vested in the Crown. Licenses for exploration for oil and gas may be granted by the Minister of Power, and the National Coal Board will have the sole right to mine any coal which may be found.

Refineries in operation and their capacity at year end, together with reported completions of expansion projects during the year were:

Company and refinery	Location	Additions to capacity (thousand metric tons per year)	Total capacity at yearend (thousand metric tons per year)
British Petroleum Co.:			
Kent	Isle of Grain		9,653
Llandarcy	South Wales	2,235	5,588

The Mineral Industry of Yugoslavia

By Roman V. Sondermayer [1]

YUGOSLAVIA produced a large variety of mineral products in 1963, some of considerable significance by world standards. The more prominent minerals, with production expressed in approximate percentages of the 1963 world totals, were as follows: Mercury 6 to 7 percent; antimony, barite, bauxite, lead, and magnesite, 4 to 5 percent; and chromite, copper, feldspar, pyrite, silver, and zinc, 1 to 2 percent. Yugoslavia is one of the richest mineral countries in Europe, especially in terms of nonferrous metals.

The 1963 mineral and metal output value for the country was about US$550 million, roughly 10 percent above that of 1962. The contribution of the mineral industry to Yugoslavia's gross national product was on the order of 12 percent for 1963, and the 246,000 workers employed represented about one-fifth the total for all Yugoslav industry. International trade of mineral products, both imports and exports, was also of considerable significance.

The Yugoslav Government which controls the mineral industry made efforts in 1963 to increase the efficiency of existing facilities by integrating enterprises and cutting down on capital construction. Mineral industry investments amounted to 59,082 million dinars (US$1 equals 750 dinars) in 1962, representing 13 percent of all investments, as compared with 29 percent in 1961. The trend continued downward in 1963.

The most important mineral developments during 1963 were in the nonferrous industry. Highlights include the opening of Yugoslavia's first uranium mine and reduction plant at Kalna in eastern Serbia, commencement of operations at the Toranice-Sasi lead-zinc mine in Macedonia, discovery of new bauxite deposits in Dalmatia, and completion of the second phase of the "Boris Kidric" aluminum plant.

The steel shortage continued, with imports constituting a fourth of requirements. The Government implemented measures to develop domestic iron resources, to reduce imports, and to build new steel capacity. During 1963, work started on the construction of the Skopje steel plant in Macedonia.

Despite expanding petroleum output by Yugoslavia's youngest and most successful mineral industry, small net imports were still necessary in 1963. Construction of the Pancevo oil refinery was started during the year. As in the past, bituminous coal, coke, anthracite, and petroleum coke were imported in large quantities. To ease the import burden, the Government initiated various projects for the better utilization of available low-grade coal deposits.

[1] Foreign mineral specialist, Division of International Activities.

Digitized by Google

The growth of mineral output in recent years should not obscure the fact that an inefficient outmoded component remains, which has been neither modernized nor abandoned. In addition to inadequate mechanization and inexperienced management, the Yugoslav mineral industry of 1963 suffered from shortages of electric energy and railroad transport capacity.

PRODUCTION

Yugoslavia's expanding mineral economy, particularly in recent years, has been reflected in production increases in all five major branches of the mineral industry, namely coal, petroleum, iron and steel, nonferrous metals, and nonmetals. At present, nonferrous metals occupy the foremost position in terms of output value, followed closely, however, by the other four branches. During 1963 most of the major mineral commodities showed production increases over 1962, with the exception of manganese, bauxite, chromite, mercury, bismuth, and salt.

The overall trend of mine output during 1959–63 has been one of sizable increases of ore but only moderate increases in contained metal. This reflects the exhaustion of richer parts of mineral deposits and the transition to large-scale mining of low-grade ores. Metallurgical facilities have been built up steadily, and Yugoslavia smelts most of its base metal ores except bauxite and zinc.

[1] Data not available.
[2] Includes aluminum alloys.
[3] Includes copper alloys.
[4] Includes pipes.
[5] Revised figure.
[6] Includes shamotte, magnetite, chrome-magnesite, other refinery material, and silica bricks.

Digitized by Google

The petroleum industry has made the most spectacular gains, with output in 1963 more than tripling that in 1959. In the same period, bauxite nearly doubled and lignite and copper rose by roughly half. The development of the Majdanpek mine and reconstruction of the Bor smelting complex around 1961 contributed heavily to the expanded production of both copper ore and refined copper.

TRADE

Minerals occupy an important position in Yugoslavia's overall trade, both in terms of exports and imports. During 1962, mineral exports of 37,851 million dinars were 18 percent of all exports and mineral imports of 50,220 million dinars were 19 percent of all imports. Although corresponding figures are not available for 1963, the trend is clearly upwards in volume for both mineral exports and imports.

Nonferrous metals occupy a special position in Yugoslavia's mineral export trade, their combined value in 1962 being 18,961 million dinars or roughly half the total. Nonferrous exports also registered a 22-percent increase over those of 1961. In recent years, bauxite was exported mainly to East Germany, copper to the U.S.S.R. and Indonesia, lead to the United States, and zinc to Poland. Yugoslavia is being gradually transformed from an exporter of mineral raw materials to an exporter of increasing quantities of refined products and semimanufactures. This significant change in export pattern is indicative of the progress in industrialization and reduces sensitivity of the economy to international market changes.

TABLE 2.—Exports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum:			
Bauxite	929,792	913,957	West Germany 679,023; Italy 183,840; East Germany 28,709.

Magnesite:			
Raw	5,190	493	All to East Germany.
Calcined	17,505	16,950	Poland 6,195; Netherlands 4,745; West Germany 3,275; Rumania 1,755.
Sintered	36,587	45,827	United States 19,910; Poland 11,987; West Germany 5,146; Hungary 4,694; Argentina 1,050.
Mineral fuels:			
Coal:			
Bituminous	1,600	1,280	All to Italy.
Dust	98,728	83,097	Italy 11,742; Austria 5,258.
Brown	6,892	14,417	Austria 11,835; Italy 1,581; East Germany 1,000.
Dust	60	575	All to Italy.
Lignite	5,696	11,872	Italy 11,742; Austria 130.
Petroleum:			
Crude	178,510	560,722	Austria 284,092; Israel 276,629.
Refined products:			
Gasoline	16,342	25,664	Poland 14,999; Netherlands 9,171.
Diesel fuel	4,038	154,365	West Germany 107,997; Netherlands 42,386.
Heating oil	61,904	76,939	West Germany 49,428; Czechoslovakia 8,098; United Kingdom 6,172; Israel 3,390; United States 3,264.
Lubricants	10,313	25,329	India 21,387; Egypt 3,935.
Other products	170	192	All to Greece.

Ferrous products head the list of imports. Imports were valued at 24,527 million dinars in 1962, representing 9 percent of all imports. However, iron and steel exports in that year amounted to 8,162 million dinars. Main sources of iron ore were India and Brazil; of scrap, the United States; of pig and cast iron, the U.S.S.R.; and of rolled products, East Germany and Austria. The Yugoslavs were expanding their steel industry so as to cut these imports.

758-002—65——53

Digitized by Google

Traditionally an importer of high-quality and high-rank solid fuels, Yugoslavia spent 7,692 million dinars in 1962, representing 3 percent of all imports, for coal alone, which came mainly from the U.S.S.R. During the same year, the country's imports of petroleum totaled 7,255 million dinars, representing 3 percent of all imports, but in the same year exports of petroleum were valued at 4,611 million dinars and were 2 percent of all exports. Imports primarily from the Soviet Union were paid for in soft currency, whereas exports primarily to Austria and Israel brought in hard currency. The expanding Yugoslav petroleum industry is making the country more nearly self-sufficient in oil.

COMMODITY REVIEW

METALS

Aluminum.—According to reports, large high-quality bauxite deposits covering an area of 800 square kilometers were discovered at Obrovac near Zadar in Dalmatia. This discovery adds 38 million tons to the nation's 150-million-ton bauxite reserve, the bulk of which is in deposits near the Adriatic coast.

The second phase of reconstruction was completed on "Boris Kidric," Yugoslavia's largest aluminum plant, at Kidricevo near Ptuj in Slovenia. The so-called column process was replaced by the Bayer process, so that approximately 50 percent of the plant operations became mechanized. It was expected that about 95,000 tons of alumina and about 40,000 tons of aluminum per year will be produced.

The first Yugoslav powdered aluminum plant started production at Belgrade. The capacity of the plant was reported to be 600 tons of this type of aluminum per year. One-third of the production will be used domestically, and the remainder will be exported.

Iron and Steel.—Production was not adequate for consumption, and large quantities of iron and steel had to be imported. To relieve this shortage, the Government, with the help of Soviet experts, initiated certain projects such as expanding the Smederevo plant and reconstructing Zenica, the largest iron and steel plant in Yugoslavia.

A British concern started construction of an iron and steel plant at Skopje in Macedonia. According to present plans, the plant will produce 300,000 tons of steel per year by 1965 as the first stage of development.

Discovery of a magnetite deposit was reported in the region of Mount Kopaonik in Serbia. The initial plan was to produce 100,000 tons of ore per year in 1964. In the area of the Ljubija mine, which produced about 800,000 tons of ore in 1962, large new reserves were developed. Total reserves reached 160 million tons of ore. When new construction is completed, annual output is expected to be about 2 million tons.

Lead and Zinc.—The new Toranice Sasi mine in Macedonia started production in 1963. Annual capacity of the mine, when in full-scale operation, will be 150,000 tons of ore. Lead concentrate was shipped to Trepca, Yugoslavia's largest lead smelting center. Zinc concentrate was shipped to the electrolytic plant at Sabac.

Nickel.—A new deposit of nickel was discovered in the region of the Goles Mountain near Pristina in Serbia. The reserve was estimated to be about 3.5 million tons of 1.5 percent nickel ore. This discovery is significant, because it is the first nickel deposit of proven economic importance in the country.

Pyrrhotite.—The smelting and refining complex of Yugoslavia's largest lead-zinc enterprise, Trepca, acquired a new facility. A magnetic separator to recover about 1.2 million tons of pyrrhotite annually was commissioned in the lead and zinc concentrator plant.

Uranium.—Yugoslavia's first uranium mine and reduction plant went into production at Kalna in the fall of 1963, it was officially announced. Reported capacity of the mine was about 200 tons of ore

Digitized by Google

per day. The process in the reduction plant was described as very efficient but no details have been revealed. Meanwhile, scientists from the nuclear institute at Vinca produced the first bar of nuclear fuel from domestic raw material. The fuel will be used in the first Yugoslav nuclear power plant, which is planned for 1970.

NONMETALS

The most backward branch of the mineral industry was the one dealing with the production of nonmetals. Difficulties in supplying the market with adequate quantities of cement after the 1963 earthquake disaster in Skopje were solved by import.

Cement.—The central part of the country, Bosnia, had no cement plant. To lower transportation costs, plans were made to construct a new cement plant near Zenica.

Fertilizers.—The new fertilizer plant at Kosovska Mitrovica, Fabrika Superfosfata, started production, and its ultimate annual capacity reportedly will be 250,000 tons of superphosphates and 120,000 tons of sulfuric acid.

MINERAL FUELS

Coal.—Coal remained the backbone of Yugoslav energy production, although natural gas was emerging as a significant competitor. Because of large reserves of low-grade coals, efforts were concentrated on finding the most efficient way of converting coal energy to a form of energy which can be more economically delivered to the consumer.

A project for gasification of Velenje lignite was awaiting approval for funds from the National Bank in 1963. Construction of a gas plant and a 250-kilometer pipeline will start immediately following allocation of the funds.

The bituminous coal from Ibar Valley was found to be of good quality for coking. In an effort to reduce coking coal imports, the Government modernized the mines in the area. For example, a modern plant was built for coal separation. The facilities include units for grinding magnetite necessary for heavy media separation. Enough magnetite powder is made in this plant for the needs of all coal beneficiation plants in the country.

The second unit of the Kosovo thermal powerplant was in the last stage of construction. The plant will use lignite dust as fuel. Plant capacity was expected to be about 125,000 kilowatts.

Three large brown-coal mines (Kakanj, Breza, and Bilo) in the Bosna River Valley were merged into a single enterprise. This action was taken with the hope that overall efficiency will be improved in all aspects of brown-coal activities.

Unfavorable conditions within and outside the coal industry contributed to its unsatisfactory performance. Many of the 89 coal mines operating in the country during 1963 were small and unprofitable. One of the measures used to improve the weak financial position of Yugoslavia's coal industry was to merge the different enterprises.

Petroleum.—Production of crude oil and natural gas reached planned targets. However, the year was without any discoveries of major new fields. The gas found near Gospodjinci may be significant, be-

Digitized by Google

cause test holes proved for the first time the presence of hydrocarbons in Backa.

Completions of a gas pipeline from Mokrin to Pancevo and a gasoline plant at Elemir were the most significant developments in the petroliferous region of Banat. The Mokrin-Pancevo pipeline, which is 185 kilometers long, connects the major oil and gas fields in Banat with the fertilizer plant at Pancevo. The Elemir plant started production in early December 1963; reported annual capacity is about 20,000 tons of liquefied gas products.

Construction was started on a new refinery in Pancevo on a site embracing over 100 hectares. The capacity of this refinery is sizable—about 1.2 million tons of crude oil per year.

The Mineral Industry of Algeria

By Thomas G. Murdock [1]

ALTHOUGH the contribution of Algeria, including the Sahara, to the local economy and to world mineral supply was small for many years, the spectacular development of an important petroleum and natural-gas industry has changed the position of the country. In 1963 there were decreases in output of most mineral commodities, however oil and gas production forged ahead and established new records. The impact of adverse market conditions and especially the competition from lower cost producing areas was felt by both the metals and nonmetals industries. This and the general economic conditions related to the recovery of the country following the years of strife attending its emergence as an independent state combined to hold back production and development commensurate with resources.

The principal events of the year were in the petroleum sector and included the first commercial production from several new fields, some new discoveries, the virtual completion of the first petroleum refinery in the country, and installation of additional pipelines. Progress was made toward the further utilization of the vast resources of natural gas and the provision of additional transportation and refining facilities. In the mining domain the government took over two iron-mining operations, and progress was made towards expanding production of phosphate rock and determining methods of upgrading the Tindouf iron ores. Completion of the iron and steel plant near Bône was further delayed. The only coal mine reportedly closed down in late 1963.

Algeria has become a major crude-oil producing and exporting country, ranking 9th in production with 1.9 percent of the world total in 1963. Nowhere else in the world in the last few years have fields of the magnitude of those in the Algerian Sahara been discovered with such rapidity. The proven oil and condensate reserves of the Algerian Sahara at the end of 1963, totaling more than 1,400 million tons (approximately 108 billion barrels), are not yet on the same scale as those of the Middle East, but are comparable to those of the East Indies, are more than half those of Venezuela, and are more than twice those of Canada. In assessing the natural gas reserve, however, the magnitude is greater; the more than 2 billion million cubic meters proven is about the same as the reserve in the U.S.S.R. and second only to U.S. reserves.

Major U.S. oil companies have extensive holdings in the country; the total investment in oil and gas exploration at the end of 1963 was

[1] Mining engineer, Division of International Activities.

Digitized by Google

estimated at between US$75 million and $100 million, representing somewhat less than 10 percent of the total capital invested in Algeria for that purpose. U.S. companies had interests in about 31 percent of the 684,600 square kilometers open to exploration at yearend.

The 1962 mineral production is estimated to have been valued at about Fr2,296 million (US$470.68 million),[2] of this, crude petroleum accounted for Fr2,060 million. The 1962 gross national product (GNP) was Fr15,868 million; thus the extractive industry contributed about 14.5 percent of the GNP. Without its oil revenues the country could scarcely exist economically. Government income at the end of 1963 was reported at Fr246 million, being obtained from a 50–50 profit-sharing agreement based on realized prices. The oil revenues were estimated at about Fr188 million for 1962 and Fr215 for all of 1963.

At the end of June 1963, the labor force engaged in mining was down to 5,574 (7,153 average in 1961), slightly more than 0.1 percent of the total labor force of 4 million, half of whom were unemployed. In 1960 an additional 7,870 workers were employed in quarrying, including salt mining. Employment data for oil industry are not available; the total working force of the Sahara region was about 194,000, of which approximately 181,000 were nomads—indicating that about 13,000 are employed by the industry and supporting activities.

GOVERNMENT POLICIES AND PROGRAMS

The only recorded cases of nationalization of the mining industry in 1963 were two iron-mining operations and three stone quarries near Bône; nationalization in other sectors of the economy was established extensively. Matters relating to mines and minerals continued to come under the general control of the Directorate of Mines and Geology of Algeria; however, on September 6 the Ministry of Industrialization and Energy, which had formerly supervised the activities of this directorate, became a division of the new Ministry of National Economy. Under the new organization, construction materials were placed under the jurisdiction of the Directorate of Industrialization, a part of the Ministry of National Economy.

The petroleum code for Algeria remained essentially as it was under the French regime, except as modified by: (1) the Evian accords; (2) the Franco-Algerian agreement of August 28, 1962, putting into application the petroleum provisions; and (3) the agreement of June 26, 1963, establishing a Franco-Algerian petroleum arbitration commission. The present petroleum code, however, even as amended, applied only to permits granted before July 1, 1962, or to renewals of these. It was reported in the latter part of 1963 that the government had not announced any decisions as to regulations governing new exploration and exploitation permits, and it was not known whether the existing code would be simply extended, minor changes would be made, or a sweeping revision would follow. Reports issued in August indicate the granting of new permits had been suspended temporarily.

[2] The unit of currency used throughout this section is the new franc (Fr), roughly on par with the French new frac. (Fr1=US$0.205; US$1=Fr4.878).

Digitized by Google

On a visit to the United States in October, the Algerian Minister of National Economy reiterated that there was no thought at the time of nationalizing the oil industry. The oil resource has been recognized as the best potential source of income to put the economy on a sound basis and everything is to be gained from insuring the continued smooth operation of the industry. However, the government would like to see more diversification of foreign interest in the petroleum resources and has made the first moves towards pressure for a larger share of the oil revenues, calling for a revision of the Evian agreement which guaranteed the development of the oil industry after independence. Establishment of a national oil company, 51 percent owned by the Algerian Government and the remainder by private oil companies, particularly American and West European, has been suggested. Under the Evian agreement French companies must be given priority, or at least the right to match any rival offer for exploration rights for a 6-year period. The agreement gives also a similar priority for concerns whose capital is held by the Algerian Government or State organizations. Indications are, however, that Algeria is looking also to Japan for partners in an exploration and production venture and to the Ente Nazionale Indrocarburi of Italy for a refining-marketing tieup.[3]

The Franco-Algerian Organisme Technique de Mise en Valeur des Richesses du Sous-Sol Saharien continued its program of promoting development of the mineral and petroleum resources of the Sahara, carrying out geological mapping, exploration, and other activities.

On September 27, Algeria became a member of the International Monetary Fund, the World Bank, and the International Development Association.

SOURCE MATERIAL

Dispatches from the U.S. Embassy in Algiers have provided a partial coverage of 1963 activity. It has been necessary to supplement these with data from interim publications of the Algerian Government; often the latter cover only part of the year. In several cases, particularly the trade since 1961, it was necessary to resort to estimates. Value of production was estimated in the absence of any factual figures; this was also done for value of exports of crude petroleum, which is not reported on an annual or other regular basis by the source materials available. Information on other phases of the oil industry is adequate and the international journals have provided much of that used.

PRODUCTION

While the annual mine production has shown some temporary growth for intermediate years of the 1959–63 period, its overall trend has been generally downward, reflecting both market conditions and the impact of the troubled conditions existing in the country. Only copper has shown a steady year-by-year increase; antimony production ceased entirely with 1963. Phosphate rock production declined because of ore depletion at the active mine; new deposits were known but not yet fully developed. The spectacular growth in production

[3] Oil and Gas International. V. 4, No. 1, January 1964, p. 36.

Digitized by Google

of petroleum, resulting from the extensive exploration activities in the Sahara, was the outstanding performance during the period; barely affected by the strife in other parts of the country and limited only by pipeline capacity, the sixteenfold increase between 1959 and 1962 brought a considerable net gain to the extractive industries, amply compensating for declining mine activity.

TABLE 1.—Production of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity [2]	1959	1960	1961	1962	1963
Metals:

[1] Includes the Sahara.
[2] In addition Algeria produces various construction materials, but annual data have not been available since 1960 when the following quantities were reported: clay (brick), 834,900 tons; clay (for cement), 297,900 tons; limestone (agricultural), 13,800 tons; limestone (for cement and lime), 1,145,200 tons; kaolin and quartz, 8,700 tons; sand and gravel, 1,382,900 tons; stone (building), 882,000 tons; stone (crushed), 4,331,300 tons; and stone (flagstone and paving), 225,000 tons.
[3] Estimated recoverable silver content of lead and zinc concentrates.
[4] Quantities for 1959–61 are mine production; comparable data for 1962–63 are not available, and quantities shown are for ground barite.
[5] Estimate.
[6] Total production including marketed.
[7] Data not available.

TRADE

Available official data on exports do not include crude petroleum. Other metal and mineral commodities were valued at Fr209 million (metals, Fr183 million, and nonmetals, Fr26 million) in 1961, having decreased from Fr233 million (metals, Fr200 million and nonmetals, Fr33 million) in 1960. Estimated value of exports of crude petroleum in 1961, including those from the Sahara the principal producing area, was about Fr1,508 million (Fr808 million in 1960). Including the crude petroleum, 1961 mineral export value was 52 percent of total export value (38 percent in 1960).

In 1961 the total value of metal and mineral imports was Fr647 million, 13 percent of all imports, compared with Fr824 million, also 13 percent, in 1960. The 1961 import value by categories was metals, Fr292 million; nonmetals, Fr58 million; and mineral fuels, Fr297 million.

France continued to be the principal partner in mineral and metal trade in 1961, supplying 90 percent of the imports and receiving 29 percent of the exports, exclusive of crude oil—74 percent going to France. Although exact data are not available, the other European Economic Community (EEC) countries, especially Italy, accounted for most of the remainder of this trade; these countries received 23 percent of the 1961 crude oil exports. Metal and mineral trade with the United States has remained small.

Only partial data on 1962 trade are available; that imports decreased appreciably below 1961 is evidenced by the decline in exports of iron and steel and solid mineral fuels from the EEC to Algeria to Fr83 million (Fr298 million in 1961). If these commodities and countries accounted for the same proportion of imports as in 1961, the 1962 imports would have been valued at only Fr182 million. The 1962 exports are estimated to have been valued at Fr189 million for metals and nonmetals and an additional Fr2,024 million for the crude petroleum.

COMMODITY REVIEW

METALS

Copper.—Copper production was 3,700 metric tons of 28 percent concentrate (2,900 tons at 27 percent in 1962), all from the Ain Barbar mine of Société des Mines de Sidi-Kamber, where copper occurs in association with lead and zinc. These are also recovered as concentrate. The improved security and economic conditions of the area, near Bône, are credited with the growing output of copper, however, the weak market position of coproduct lead and zinc held back copper production. The Ain Barbar reportedly has a capacity of 50,000 metric tons of ore per year and at full-scale operation could produce 4,500 tons of copper concentrate, 1,500 tons of copper-lead concentrate, and 2,000 tons of zinc concentrate. Data available do not indicate production of copper-lead concentrate for 1962 and 1963; in 1961, output reportedly was 216 tons of an unstated grade and was included with 451 tons of lead concentrate assaying 78 percent lead. In 1962, exports of copper concentrate were 3,572 tons; through the first 6 months of 1963 they declined to an annual rate of 2,070 tons.

The Algerian Government planned exploration of another copper deposit in the mountains near Blida south of Algiers, where a high-grade occurrence was known; this was scheduled to begin in the second 6 months.

Iron Ore.—The 1963 decline in iron-ore production followed the trend begun in 1960; it was due mainly to continuing difficulties in marketing the ore (average 1959–62 iron content, 53.9 percent) in competition with higher grade material readily available on the European markets from other countries. The decreased popularity of Algerian ores was reflected in the 32-percent drop in the f.o.b. selling price in the United Kingdom and West Germany between 1957 and 1962. The 1962 exports were 2,131,200 metric tons and distribution was approximately as follows: United Kingdom, 62 percent; Italy, 22 percent; West Germany, 9 percent; France, 5 percent; and Belgium-Luxembourg, 1 percent. Exports through June 1963 were at the

Digitized by Google

annual rate of 1,849,000 tons; receipts by European Common Market countries through September were at a rate of 7 percent below 1962. It was reported in September that a trade agreement had been signed with Bulgaria for delivery of an unstated quantity of ore from the Beni-Saf, Rouina, and Zaccar mines.

Because of marketing difficulties the Compagnie des Mines de Fer Mokta el Hadid gave up its concessions at the Beni-Saf mines near Tlemcen and the Algerian Government took over as of February 1, placing operations in charge of the Government Mining Service (Service des Mines) pending the creation of a public organism for mineral exploitation. In July the government also took over operation of the Zaccar mine near Miliana. Following a sharp drop in production in 1962 the managing company, Société Anonyme des Mines de Zaccar closed the mine in June, without abandoning its concession rights. The government reacted by placing the mine under the Bureau d'Etudes et de Recherches Industrielles et Minières (BERIM). The Rouina mine, idle since 1958, was also reopened with the aid of Bulgarian technicians, which was also extended to the Beni-Saf and Zaccar mines.

Production by mines for the latest years for which data are available was as follows:

Mine:	Metric tons	
	1961	1962
Beni-Saf	181,467	159,119
El-Maden	20,674	9,377
Khanguet	146,738	142,837
Ouenza	2,133,601	1,505,544
Timezrit	128,410	91,046
Zaccar	240,367	153,960
Other	15,970	----------
Total	2,867,227	2,061,883

The Gara Djebilet iron-ore deposits, with a proven reserve of more than 1 billion metric tons containing about 58 percent iron, and situated about 130 kilometers southeast of Tindouf in the western Sahara, were in the news as an element in the Algerian-Moroccan border dispute in the fourth quarter. In April a pilot-plant installation set up by Société d'Etudes et de Realisations Minières et Industrielles (SERMI), the organization investigating these deposits, was completed and began an elaborate series of beneficiation tests to upgrade the ore by dry magnetic separation. A description of the deposits, earlier testing of the ore, and the new installation appeared in the technical press.[4] The deposits could be mined by open cut; however, their development would require a railway to the Atlantic, 380 air-kilometers away. Consequently the importance of improving the ore tenor is clearly a factor in their eventual possible development.

Iron and Steel.—In the absence of data on 1962 imports of iron and steel an approximate figure is reflected in the exports of the European Economic Community to Algeria. These exports consisted of 380 metric tons of pig iron and ferroalloys, 38 tons of scrap, and 98,136

[4] Annales des Mines (Paris), Station d'Essais pour Enrichissement du Mineral de Fer de Gara Djebilet (Pilot Plant for Beneficiation of the Gara Djebilet Iron Ore). April 1963, pp. 21–34.

Digitized by Google

tons of crude steel and rolled products, valued at Fr75 million (Fr280 million in 1961). The indicated decrease in imports was the result of decreased construction activity and curtailment of activity by Algerian metal-working establishments.

In 1960 the latter produced 7,500 metric tons of iron castings, 7,500 tons of steel castings, 40,400 tons of rolled steel, and 11,600 tons of wire products. In 1961 total apparent steel consumption expressed in terms of ingots was 402,000 tons, or 36 kilograms per capita (571,000 tons and 52 kilograms, respectively, in 1960). At the end of 1963 Aciéries et Laminoirs d'Oran (ACILOR) was turning out rolled products at the annual rate of 21,600 tons.

Although progress was made toward completion of the 400,000-ton-per-year steel plant 10 kilometers south of Bône, scheduled for late 1963, numerous difficulties intervened to delay this. Lack of an adequate water supply due to the noncompletion of the dam on the Oued Bounamoussa was reported in May as having held up completion of the plant, and subsequently, operations were rescheduled to begin only at the end of 1964.

This project, undertaken by Société Bônoise de Sidérurgie, partly financed by French public or semipublic sources, has been under construction since 1959; initially it is to consist of one blast furnace and two bessemer converters and would produce billets for export. Iron ore from the Ouenza mine would be smelted and expectations were that the annual demands of at least 800,000 metric tons would partly compensate for the loss of iron ore markets in Europe and permit iron mines to continue at the previous high production level.

Lead-Zinc.—The decreased production of lead and zinc (as well as recoverable silver contained in the concentrates) was essentially the result of low metal prices. The largest mines, situated along the Algerian-Moroccan frontier, were undoubtedly affected adversely by the boundary dispute and the labor difficulties which shut down the nearby lead smelter in Morocco, where a part of the Algerian production is smelted.

The 1963 output consisted of 11,800 metric tons of lead concentrates (12,917 tons in 1962) and 57,460 tons of zinc concentrates (70,057 tons in 1962). Tenors are believed to have averaged 68 percent and 63 percent, respectively. The zinc concentrates were mainly of sulfide minerals; however, the quantity of calamine included in the total rose from 470 to 1,660 tons. Indications are that five mines were in production, as in 1962 and 1961. Production by individual mines in 1961 was as follows:

Mine	*Ownership*	*Concentrate production (metric tons)*	
		Lead	*Zinc*
El Abed	Société Algérienne du Zinc	4,713	40,150
Oued Zounder	Société Nouvelle des Mines d'Ain-Arko.	3,546	27,013
Sidi-Kamber	Société des Mines de Sidi-Kamber	3,503	1,720
Ain Barbar	do	[1] 451	661
Ouarsenis	Société des Mines de l'Ouarsenis	859	1,363

[1] Includes an unspecified quantity of copper-lead concentrates.

Digitized by Google

In 1961, El Abed milled 130,322 metric tons of ore; Ain Arko, 140,198 tons. Mill recoveries were, respectively, 90 and 86 percent for the lead and 97 and 85 percent for the zinc.

In 1962, exports were 12,164 metric tons of lead concentrates and 68,992 tons of zinc concentrates; in the first 6 months of 1963, exports were at respective annual rates of 12,172 tons and 42,176 tons.

NONMETALS

Barite.—The appreciable increase in production of ground barite in 1963 was the result of efforts to increase domestic self-sufficiency. Lack of data on imports does not permit a reliable appraisal of results but 1963 production exceeded 1962 consumption (28,793 metric tons). In past years French barite was obtainable at a lower cost than the domestic product; however, reports are that the Algerian producers have been able to deliver barite of an average density of 4.3 at a competitive price. The principal producer continued to be Société Anonyme des Barytes Algériennes, having a modern plant at Oued Smar (Algiers). Exports through June were at the annual rate of 1,380 tons (about 1,200 tons in the year 1962).

Cement.—A new cement plant was entered in service at Bougie early in 1963, contributing to the increased 1963 production. Data on imports were available only for the first 6 months of 1962 when they were 186,000 tons for the year, considerably below the level of preceding years. The small production and imports of cement, in comparison with 1960–61 indicates that construction activity remained at a low level. In 1961, 31,554 housing units were started (37,596 units in 1960).

Phosphate Rock.—The 36-percent drop in phosphate rock production (29.8 percent P_2O_5) was mainly due to the declining reserves at the only mine in production, the Kouif operations of Compagnie des Phosphates de Constantine. At yearend the reserves were virtually exhausted, and mining was expected to cease in 1964. Work continued on preparations for mining the deposits at Djebel-Onk where Société de Djebel-Onk is installing mine and upgrading facilities expected to produce initially 600,000 metric tons per year, later to be expanded to 800,000 tons. The crude rock, containing 25.6–26.6 percent P_2O_5 is to be beneficiated to 34.4 percent in three stages. A pilot plant at Bône has developed the flowsheet for this. Originally scheduled for completion in late 1963, delays have postponed this until 1964. The new installations were estimated to cost Fr130 million, and the company was capitalized at Fr30 million.

In 1962 exports were 407,000 metric tons; local consumption, 26,423 tons. Through the first 6 months of 1963, exports were at the reduced annual rate of 340,00 tons. Local consumption is in manufacture of superphosphate; production of this declined sharply from 101,000 metric tons in 1958 to 59,700 tons in 1961 and 46,900 tons in 1962, result of conditions in the country. Output during April–July 1963 was at the annual rate of about 58,300 tons.

Sulfur and Pyrites.—Despite the completion of a program of equipment modernization by the only producer of pyrites (45 percent sulfur content), the El Halia mine near Philippeville, output decreased by 12 percent in 1963 to below the 1960 level. The reduced production

Digitized by Google

was reportedly the result of competitive market difficulties and, despite a 10-percent reduction in price, a greater volume could not be sold. Total (both roasted and unroasted) exports were 34,692 metric tons in 1962 and through June 1963, at the annual rate of 33,562 tons. In 1961 local manufacture of 30,000 metric tons of sulfuric acid utilized 14,269 tons of domestic pyrites; the 1962 consumption of pyrites was about 20,000 tons.

The Algerian Government announced plans to reopen the sulfur mine at Heliopolis, idle for some years following bomb damages during the hostilities.

MINERAL FUELS

Coal.—Following extensive substitution of Saharan oil and gas for domestic coal produced only by the nationalized colliery at Kenadsa in the Sahara, 1963 saw the further curtailment of coal output. In December 1961, it was decreed that production would be progressively reduced and cease completely by the end of October 1963. The mine operated for several years with an annual subsidy of about Fr10 million, and the 1961 operating deficit was estimated at Fr8 million.

Coal imports have also declined with the increased share of energy being supplied by oil and gas, particularly since 1960. Data on actual 1962 total imports were not available; they were reflected in the 153,866 metric tons exported to Algeria by the EEC and 45,609 tons by Morocco—a total of 199,475 tons, 41 percent below 1960 imports.

Petroleum and Natural Gas.[5 6]—Although the crude oil production in the year did not show the spectacular rise characterizing past years, the 15-percent increase established a new record high and was about the maximum possible, considering that some major pipeline systems to the Mediterranean have become essentially full, and large output boosts could not be expected. Output of the Polignac basin of the Sahara, the principal producing area in 1962, was 11,379,000 tons (10,560,000 tons in 1962); however, with the increased output from the Triassic basin to the northwest, partly due to the new Rhourde el Baguel field there, this basin accounted for 51.8 percent of the country total (48.4 percent in 1962) and regained the first place it had in 1961. The small basins in northern Algeria continued to be of minor importance.

Exports of crude oil were 23,655,208 tons (20,350,000 in 1962). The 1963 exports were to France, 15,535,488 tons; other Common Market countries, 6,158,509 tons; and other countries, 1,961,211 tons. Of 1963 exports, 59 percent (52 percent in 1962) were shipped from Bougie, in Algeria, the terminus of the 638-kilometer pipeline from Haoud el Hamra (Hassi Messaoud), and 41 percent (48 percent in 1962) were shipped from La Skhirra, in Tunisia, the terminus of the 757-kilometer pipeline from In Amenas. Local sales in 1963 were 157,491 tons.

In 1963, market sales of natural gas amounted to 394 million cubic feet; based on data through August, 308 million were supplied by the Hassi R'Mel field of Société d'Exploitation des Hydrocarbures d'Hassi R'Mel (SEHR), 50 million came from the In Amenas North gasfield

[3] Operating company is Sinclair Mediterranean Petroleum Co. EURAFREP and Tidewater also hold interest in the concession.

of CREPS, and 36 million came from the Hassi Messaoud North oilfield of CFPA. In 1962 marketed gas production was 353 million cubic meters, all from Hassi R'Mel.

Gasoline condensate production in 1962 was 201,869 tons; 182,024 tons came from Hassi R'Mel; 11,002 tons, from In Amenas North; and 8,843 tons, from the Hassi Tourag field of Compagnie des Pétroles France-Afrique (COPEFA). Through August 1963, Hassi R'Mel produced at the annual rate of 220,800 tons and In Amenas North at a rate of 12,000 tons; Hassi Tourag was apparently idle.

The pace of exploration activity over the Sahara generally continued much as before although there was a decline in geophysical activity as a result of the completion of the general reconnaisance of many exploratory leases. Geophysical operations were mainly concentrated on areas of previously recognized interest where detailed studies were required, such as the Polignac basin, the western flank of the basin of the great Eastern Erg, and the borders of the Hassi R'Mel plateau. However, exploration was continued also in the newer areas of the Tindouf basin (part of which was the scene of the Algerian-Moroccan border strife in the fourth quarter) and the southwest corner of the great Eastern Erg.

Major discoveries made in the last half of 1962 and in 1963 include the location of a large oil reservoir at Rhourde el Baguel, which began

Digitized by Google

limited production in July, and at Gassi Touil, as well as important natural gas deposits at Rhoude Nouss and Rhoude Chouff on the Rhoude Hamra permit and at Alrar north of it. These finds on the western culmination of the basin of the great Eastern Erg in the El Biod plateau of the north Triassic province resulted in concentration of a considerable amount of exploration work in this area in the latter part of the year. In July a new deposit was discovered by SNPA, between the El Gassi and El Agreb fields, and the first tests showed 555 tons per day.

In the Polignac Basin the rate of discoveries remained outstandingly high (although most of the later ones were of natural gas), and a great deal of exploratory work continued to show the importance of this oil province. Exploratory drilling was concentrated, particularly in the southeast of the basin where CREPS was searching for the bevel of the Lower Devonian reservoirs on the culmination of the plateau adjoining the Libyan border and on the eastern region of the Tinhert plateau in the Ohanet area.

Well completions totaled 193 in 1963, an increase of 16 percent over the 167 in 1962 when 108 development wells totaling 181,000 meters and 59 exploratory wells totaling 135,000 meters were drilled. Development drilling activity declined because areas of several fields—for example Hassi Messaoud, Ohanet, Edjeleh, and Zarzaitine—were practically developed. At the beginning of the year, 519 oil wells were in production; of these 500 were flowing and 10 were artificial lift. Total oil wells drilled within the productive basins to January 1, 1963, were 793 of which 537 were capable of oil production.

In December the total proven reserves of oil and gas in the Algerian Sahara were reported to be as follows:

Field area:	*Oil and condensate (million tons)*	*Natural gas (million cubic meters)*
Polignac	450.6	498,400
Hassi Messaoud, El Gassi-El Agreb	480.0	-------
Hassi R'Mel	400.0	996,800
Ohanet Region	15.0	-------
El Biod Plateau	85.0	736,200
Ahnet-Mac Mahon Basin	-------	51,000
Total	1,430.6	2,282,400

Additional pipelines were completed and announcement of plans for others was made during the year. In March the 206-kilometer line from the Tin Fouyé field to In Amenasn was completed, followed a little later by the 108-kilometer line to permit evacuation of the new production from the Rhoude el Baguel to the Hassi Messaoud (Haoud el Hamra terminal). In July branch lines were finished to connect Algiers, Oran, and Arzew with the existing Hassi R'Mel-Relizane-Damesne lines; these new branches have a total length of 308 kilometers, and the old main line is 488 kilometers long. The new oil lines raised total length of these lines to 2,537 kilometers, including the 16-centimeter line from Hassi Messaoud to Touggourt, the terminus of the railway to the Port of Philippeville. This route was used before completion of the Haoud el Hamra-Bougie line, and is still available for use, if required. An additional 285 kilometers of line is used to move gasoline from Hassi R'Mel to Haoud el Hamra.

Digitized by Google

In 1963 plans were completed for construction of a new 60-centimeter line from the Haoud el Hamra terminal to Arzew, 766 kilometers away, paralleling the natural-gas and natural-gasoline pipelines already in existence on this route. Initial capacity will be 6 million tons per year, rising to 8.6 million by 1966 and to an eventual 14 million at a later time. At yearend, construction had not begun but was held up pending the outcome of discussions between representatives of the Algerian Government and the pipeline company representing the Saharan producers, Société pour le Transport des Hydrocarbures Sahariens au Littoral Algérie (TRAPAL), as to the percentage shareholding to be taken in TRAPAL by the former.

Announcement was made of plans to build a pipeline from Mostaganem to Cartagena, Spain, to transport Hassi R'Mel gas to Europe. Final tests on the technical feasibility of the project were scheduled for July. This 24.5-centimeter line would be 200 kilometers long and would be designed for pressures of 400 kilograms per square centimeter. The line may be built by a combination of companies, including Gaz de France; at yearend final decision had not been announced.

The serious fire damage suffered by the M'Sila pumping station (on the Bougie line) in October 1962 was repaired, and full capacity of the line was reestablished in the first half of 1963. On August 23, a fire in the SN REPAL pumping station at Hassi Messaoud resulted in some loss of production by that company.

SN REPAL continued operation of the 165,000-ton-per-year topping plant at Hassi Messaoud, producing fuels for local use. In 1962 this facility treated 83,340 tons of crude. Work on the construction of the Fr195 million Algiers refinery in suburban Maison Caree (renamed El Harrach) was intensified during the year and its completion scheduled for early 1964. This refinery is owned by Société de la Raffinerie d'Alger (SRA), a consortium of several French and other foreign major oil companies, including Mobil, ESSO, and Shell. Original plans were to treat 2.5 million tons of crude, but because of the reduction in the market capacity the figure was cut down to 1.5 million tons. Most basic facilities originally planned have been installed, and expansion to 2.5 million tons of capacity would be relatively simple. About 80 percent of the refinery production will be needed to supply the Algerian market, leaving a small amount for export. The SRA refinery is to be supplied by tanker from Bougie and delivery from Algiers port to the refinery is by a 65-centimeter pipeline, 16 kilometers long.

At yearend the methane liquefaction plant at Arzew, the small port 32 kilometers from Oran, and equipment of the port to accomodate methane tankers were nearing completion. This facility, estimated to cost Fr312 million, is to be operated by Compagnie Algérienne du Methane Liquide (CAMEL), formed by Shell, COMSTOCK, and three French companies; it will permit a tremendous increase in the use of the natural gas from Hassi R'Mel. Annual deliveries to the United Kingdom are expected to be 1.5 million cubic meters, and one-half that volume will go to France. In December announcement was made of a World Bank dollar loan of Fr97.6 million to CAMEL. The Algerian Government guaranteed this loan, and some press reports

Digitized by Google

indicated negotiations with CAMEL for an ownership participation of about 25 percent.

In September an agreement for a second refinery was concluded between the Algerian Government and Ente Nazionale Indrocarburi (ENI), the Italian oil enterprise. The refinery is to be built at Arzew and operated by Société Nationale de Raffinage (Algerian Government, 51 percent, and ENI, 49 percent), and an investment of Fr115 million is envisaged; no date for beginning of construction has been announced. Reportedly [r] ENI did not seem to show much enthusiasm for the project but was attracted by concessions for natural gas it hoped to obtain.

Consumption of petroleum products, still largely imported in 1963, was probably not in excess of that of 1962 when it showed an appreciable decline from 1961 as a result of the massive departure of Europeans during the year and the depressed condition of the economy. The 1962 consumption follows: Gasoline, 284,679 metric tons (323,762 tons in 1961); kerosine, 94,230 tons (106,308 tons in 1961); gas and light fuel oil, 223,432 tons (273,840 tons in 1961); heavy fuel oil, 101,865 tons (307,081 tons in 1961); and domestic fuel oil, 161,446 cubic meters (206,624 cubic meters in 1961).

The Mineral Industry of Angola

By Thomas G. Murdock[1]

EXCEPT for an important increase in the production of crude petroleum and refined products, the extractive industries of the Province of Angola, Portugal's largest overseas dependency, showed little improvement in 1963. Angola has never been of great significance as a mineral supplier by world standards, and although production of a few minerals has expanded considerably over the last decade, the total value is still comparatively small. Its overall diamond production in 1963 was only 3 percent of the world total. However, Angola ranked eighth among producing countries and third in gem variety. Modest quantities of copper, iron, and manganese ores, as well as mica, have been contributed to world supply. However, the 1963 output was well below the average of recent years and was nil in some cases. The most important development was a record high petroleum production, the crude output being almost 16 times that of 1959, thus providing a surplus for export. Progress toward the provision of facilities for greatly expanded iron ore exports was also significant.

The 1962 mineral production exclusive of refined petroleum was officially valued at Esc1,243 million (US$43.46 million).[2] Crude petroleum comprised Esc254 million of this total. Refined petroleum production was valued at Esc384 million. Recent data on the gross national production (GNP) or the gross domestic production (GDP) of Angola are not available. For 1958, however, the GDP was approximately Esc11,428 million. The mineral production in 1958 was valued at Esc827 million or 7 percent of the GDP. If the 1962 GDP was 18 percent above that of 1958, as were all exports, the contribution of the extractive industries to the 1962 GDP would have been 9 percent.

Employment by the extractive industries in 1960, the latest year for which data are available, consisted of 1,300 European and 43,000 African personnel, or 2 percent and 13 percent, respectively, of the total labor force. Diamond mining was the largest employer in this sector, employing 558 Europeans and 27,052 Africans in 1962.

GOVERNMENT POLICIES AND PROGRAMS

No significant mining legislation was enacted in 1963, and the basic Portuguese Decree of September 20, 1906, providing that the State

[1] Mining engineer, Division of International Activities.

[2] The Angolan monetary unit is the escudo (Esc), roughly on a par with the Portuguese unit of the same name and equivalent to about US$0.035. Consular dispatches from Luanda show local exchange was Esc1=US$0.03496 (US$1=Esc28.60) prior to Nov. 13, 1963, and Esc1=US$0.0354 (US$1=Esc28.54) after that date.

Digitized by Google

owns all mineral deposits, has been continued with amendments that apply especially to Angola. Several 1963 legislative acts, however, did affect the Angolan mineral economy. A new interterritorial payments system went into effect in March. This was expected to alleviate the exchange shortage which had affected severely the Metropolitan Portugal-Angolan trade. A new defense tax was decreed on June 15, providing for a 10-percent tax (plus a stamp tax of approximately 3 percent), to be levied on all enterprises with profits equal to or above Esc1 million, except for new enterprises which have operated less than 5 years and those exempted by special contracts, such as the Companhia de Diamantes de Angola and the Benguela Railway. As part of the program of economic integration of the Portuguese National Space (Metropolitan and all overseas Portugal), customs duties on goods imported into Metropolitan Portugal from Portuguese Provinces were eliminated, effective January 1, 1964.

Provisions were made for a greater participation of foreign capital in some projects. The organization of an international consortium for iron ore exploitation was officially approved, and foreign association in a new company to prospect for gem stones was authorized. Arrangements were worked out for the large-scale use of Angolan crude petroleum by the refinery in Metropolitan Portugal.

Exploration was continued by several concerns, but no spectacular finds were reported. The work was essentially a search for extension of known mineralized areas and to prove areas for which prospecting permits had been issued. Budgetary limitations held back the Government's originally planned program of road construction and maintenance. However, expenditures amounted to Esc312 million.

SOURCE MATERIAL

Information on production and current developments has been supplied by the U.S. Consulate General, at Luanda and is supplemented by official publications of the Province of Angola. These data are reliable and reasonably complete. Data on 1960 and 1961 trade are from the Foreign Trade Statistics, published by Province's Directorate of Economic Services and General Statistics. For subsequent years trade data are from monthly bulletins of this organization. These are published as summaries covering only the most important commodities, and detailed information shown is not sufficient to permit the complete listing and analysis made for 1960–61. Data on diamond mining are from the 1962 report of the company engaged in that activity.

PRODUCTION

The year 1963 was characterized essentially by the continuation of trends evident in 1962. The emergence of petroleum as a major product was accentuated by a continuance in the growth of the output. Other salient developments were cessation of manganese mining, the severe decline in copper production, the continued lack of activity in mica (Angola formerly produced some of the finest quality material in the world), and the decrease in iron ore production to the pre-1960 level, a temporary situation pending completion of planned produc-

Digitized by Google

tion facilities. There was increased production of rock asphalt for local utilization in the Province's program of road improvement. Another significant development since 1959 was the continued increase in the percentage of gem variety diamonds in the total diamond production, reaching a record high in 1963, with consequently rising annual value regardless of the total quantity produced.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963

[3] Includes 76 tons of cutbacks.

TRADE

Complete data on minerals and metals trade have not been available since 1961, when imports of these commodities were valued at Esc389 million (Esc361 million in 1960); exports were valued at Esc904 million (Esc738 million in 1960). The 1962 imports of major commodities, which constituted 92 percent of the total in 1961, amounted to Esc 221 million; in 1963, based on a projection of data through October, they were down to about Esc184 million. Exports were approximately Esc832 million in 1962, increasing to about Esc1,163 million in 1963.

In 1961 minerals and metals accounted for, by value, 12 percent of all imports and 23 percent of all exports. Fuels totaled Esc217 million, metals Esc161 million, and nonmetals Esc11 million of the 1961 imports. The values of 1961 exports follow: Diamond, Esc662 million; iron and manganese ores, Esc147 million; fuels,[3] Esc48 million; other

[3] Maritime bunkers are included in all export values.

metals and nonmetals, Esc47 million. The lower value of the 1962 exports was due mainly to the decrease of diamond exports to Esc556 million; in 1963 these rose to Esc768 million. The increased exports of fuels, resulting from the greatly expanded production of both crude petroleum and refined products, accounted for much of the increased value of exports in 1963, offsetting the drastic decline in exports of manganese ore and copper and the lower value of iron ore exports

Digitized by Google

despite an increased tonnage. This spectacular gain in value of petroleum exports (from Esc47 million in 1961 to Esc238 million in 1963) has also been reflected in the abrupt decline in petroleum imports (from Esc202 million in 1961 to an estimated Esc90 million in 1963), thus altering appreciably the country's mineral trade pattern.

Angola's minerals and metals trade was diversified, with 34 suppliers and 25 recipients in 1961, including Portugal's other overseas territories. In that year Metropolitan Portugal was the chief supplier with 15 percent of the total. Other major suppliers were Belgium-Luxembourg (14 percent), Venezuela (13 percent), and the United States (10 percent). Imports from the European Economic Community were 30 percent of the total. Receipts from the United States amounted to Esc40 million; fuels comprised Esc29 million, metals, Esc10 million, and nonmetals, Esc1 million. These constituted 12 percent of all imports from the United States.

As the recipient of all diamond exports, the United Kingdom received 73 percent, by value, of the total 1961 exports. The European Economic Community (mainly West Germany) accounted for 13 percent; Portugal received only 1 percent, and the U.S. share was 0.1 percent. Portugal's share of the exports increased in 1963, when shipments of crude petroleum were expanded.

COMMODITY REVIEW

METALS

Aluminum.—No progress was reported towards the installation of the proposed aluminum rolling mill to utilize power from the Cambambe Dam. At the annual meeting of the company sponsoring the project, Aluminio Portugues (Angola), it was announced that the initial plan to roll 25,000 tons per year from ingots imported from France would have to be revised downward because the Cambambe installation could not provide the necessary power. No new production objective was announced.

Copper.—In January, Luanda newspapers stated that the ore reserve of the Mavoio mine of Empresa do Cobre de Angola (ECA), a subsidiary of the powerful Portuguese enterprise Companhia União do Febril, was nearing exhaustion. This mine, the Province's only copper producer, has been exploiting oxide ores since about 1942 and in 1949 began smelting these in a water jacket blast furnace at the mine, obtaining black copper for export to Portugal. The 1962 production consisted of 16,206 tons of 7 percent copper ore, part of which was processed to yield 779 tons of black copper containing 93 percent copper and 84 tons of matte with 70 percent copper. Mining and smelting continued through 1963, but at a greatly reduced rate, as was reflected by the low production. ECA continued its efforts to find new ore. However, there is no record that these efforts were successful. Exploration for copper has been in progress in northern Angola and elsewhere for over a decade. Despite a wide distribution of copper occurrences under a variety of conditions, only the Mavoio has become

Digitized by Google

an active mine, and with its exhaustion the small production apparently will cease.

Iron Ore.—Although 1963 iron ore production was below that of recent years, exports established a record high of 655,546 tons (445,987 tons in 1962). Companhia Mineira de Lobito (CML) accounted for most of the production with ore mainly from its Cuima and Cassinga mines. An estimated production of 200,000 tons came from mines of the Companhia do Manganes de Angola near Malange, and according to newspaper accounts Companhia Mineira da Mombassa shipped 34,000 tons to Czechoslovakia as part of a 40,000-ton barter deal, receiving mine equipment in exchange.

With the completion of the 70-kilometer rail connection between the Cuima and Vila Robert Williams on the Benguela railway in late 1962, ore shipments were stepped up, permitting a decrease of mine stocks and the increased exports. Shipments consisted of 63 percent iron direct-shipping ore and lower grade material upgraded in a 100-ton-per-hour sink-float plant.

Late in 1962 the Portuguese Government approved the contract of CML with an international consortium including Krupp, the Danish firm of Hojgaard and Schultz, and the Sociedade Portuguesa de Empreitadas e Trabalhos Hidraulicos. The contract called for expenditures of Ecs1.3 billion for equipping the Cassinga mine, building the 95-kilometer rail link northward to join the Moçâmedes Railway, and installing ore-loading facilities at Moçâmedes port. The mine has an ore reserve of about 67 million tons of 62-percent iron. An initial production of 1 million tons annually is planned, to be expanded to 4 million tons annually, the capacity of the railway. Production from the Cassinga in 1963 was only about 150,000 tons, and part of this was trucked to the railway at Vila Artur de Paiva for movement to Moçâmedes. Construction of the railway link began early in the year. In April the purchase of property for the ore-loading facilities at Moçâmedes began, and work started on the extension of roads and power lines into the area. CML also placed orders for the construction of two bulk ore carriers of 45,000- and 20,000-tons capacity to relieve congestion of ore held in Lobito awaiting shipment to Europe.

Iron and Steel.—In March, newspaper reports indicated plans for the establishment of facilities for remelting scrap iron and steel and converting it into reusable form. Investment in the plant and equipment was expected to be Esc15 million, and expected output was 14,000 tons per year. In expectation of the completion of the plant within 1 year, the new enterprise began building up stocks of scrap, beginning with Esc25 million worth of old steel railway ties which had been replaced by wooden ties in recent years.

In July plans were announced for the establishment of an electrometallurgical complex as an auxiliary project of the Cambambe hydroelectric development on the Dondo River. The annual production was to be 40,000 tons of pig iron, 22,000 tons of ferroalloys, and 4,300 tons of calcium carbide. Energy requirement was expected to be 200 million kilowatt-hours per year.

Manganese Ore.—Following a constant decline in production of manganese ore from the Quitoto mines of Companhia de Manganes de Angola since 1959, mining ceased altogether in 1963. Competition

Digitized by Google

from other more favorably situated producers in the markets formerly supplied by Angola caused this. Exports from stocks during the year were 203 tons through October (9,526 tons in all of 1962).

NONMETALS

Diamond.—In 1963 Companhia de Diamantes de Angola (DIAMANG) continued operations at its various mines in the Luanda area at approximately the same rate as in 1962. Exports, all to the United Kingdom, however, rose to 1,293,243 carats valued at Esc768 million (985,776 carats and Esc556 million in 1962). Sales were to the Diamond Corp. under the terms of the contract expiring in 1965.

Details of the 1963 operations are not available, but comparative data for 1961 and 1962 follow:

	1961	1962
Volume of overburden removed---thousand cubic meters--	10,470	11,180
Average thickness of overburden---------meters--	5.44	5.86
Overburden removed mechanically---------percent--	51.6	43.0
Volume of diamantiferous gravel treated thousand cubic meters--	2,369	2,546
Average tenor---------carats per cubic meter--	0.48	0.38
Gravel treated per worker-month---------cubic meters--	21.22	23.10
Gem diamonds in total production---------percent--	65.43	70.52
Industrial diamonds in total production---------do----	34.57	29.48

DIAMANG continued exploration, mainly for alluvial deposits along the streams of Luanda District, but some activities extended over to Malange District, and some drilling was done in search of primary deposits. In 1962 new discoveries slightly exceeded the year's production.

A new company, Sociedad Angolana das Pedras Preciosas e Diamantes, was formed to prospect for precious stones, including diamonds, in the area outside the concession held by DIAMANG and formerly reserved for the Government. Financing was to be provided by both the National and the Provincial Governments, and foreign participation in the venture was encouraged. Reportedly representatives of an important South African group visited Angola and discussed the project but decided not to participate.

MINERAL FUELS

Petroleum.—The year 1963 saw the establishment of record highs by Campanhia de Petroleos de Angola (Petroangol), operator and owner of the fields and the 350,000-ton-per-year refinery at Luanda, and by that company's Belgian founder and prospecting and producing contractor, Compagnie Financiere de Petroles (Petrofina). The 70-percent increase in the production of crude was made possible by the development of the new discoveries, made in 1962, in the Tobias field, 110 kilometers southeast of Luanda, where the producing formation is fractured limestone at about 800 meters. The installation of a pumping station and completion of a 20-centimeter pipeline to the refinery permitted delivery of the increased output from the field. Crude oil processed in the refinery was 475,110 tons (347,000 tons in 1962). Despite the increased refinery feed, exports were 317,719 tons valued at Esc126 million (114,951 tons and Esc57 million in 1962). Production of refined products showed an overall increase of 35 percent, and

Digitized by Google

except for residual fuel oil the increase was general. Metropolitan Portugal received the greater part of the export of crude, following the decision that the SACOR refinery there might import up to 600,000 tons annually of Angolan crude in excess of the needs of the Petroangol refinery.

Further drilling was done in the Tobias and other fields, particularly the Pitchi. Expectations were that 10 wells would be completed during 1963. In 1962 about 96 percent of the total output came from the Tobias field; the remainder came mainly from the Benfica and Luanda fields. Natural gas production in 1962 was 19,523 million cubic meters; none of which was marketed. Data on reserves of the Tobias field have not been announced, pending further exploration. At the beginning of 1963 the total reserve of Angola was placed at approximately 7 million tons.[4] Addition of the Tobias field reserve will increase the total appreciably.

Consumption of liquid fuels and lubricants for 1962 and 1963, as estimated on the basis of reported data for the January to September period of these years, follows:

		1962	1963
Gasoline, ordinary	thousand barrels	336	376
Gasoline, aviation	do	126	138
Kerosine	do	108	90
Diesel oil	do	744	827
Jet fuel	do	30	44
Heavy fuel oil	metric tons	60,082	66,290
Lubricating oil	do	7,433	7,060
Lubricating grease	do	831	812
Butane gas	do	2,873	3,041

The Mineral Industries of the British High Commission Territories of Basutoland, Bechuanaland, and Swaziland

By Thomas C. Denton [1]

IN 1963 the British Territories of Bechuanaland and Swaziland in southern Africa produced several mineral commodities, of which asbestos was most important. Production in Basutoland was limited to diamond. The territories were under a High Commissioner, appointed by the Queen and responsible to the Secretary of State for Commonwealth Relations. Ultimately the Territories are to become self-governing and presumably independent. Considerable progress toward that end was made during the year.

Complete statistics of imports and exports are not kept in the Territories because for customs purposes they are treated as part of the Republic of South Africa, which collects duties for them. The unit of currency used in each of the Territories is the rand (R) [2] of the Republic of South Africa, which is divided into 100 cents.

SOURCE MATERIAL

Source material, besides dispatches of the U.S. Foreign Service, largely comprised publications of the Territories, articles appearing in the South African press, trade journals, and company reports. For Swaziland Bulletin 2, The Mineral Resources of Swaziland, published by the Territorial Geological Survey and Mines Department, was particularly useful.

BASUTOLAND

Mineral surveys conducted in recent years in this mountainous territory have resulted in discovery both of diamonds and of kimberlite rock from which diamonds derive. No other economic minerals have been found in workable deposits. Recorded exports of Basutoland diamonds were 5,110 carats, valued at R153,423.

Diamond prospecting jointly by De Beers Consolidated Mines, Ltd. (De Beers), and Jack Scott failed to reveal deposits profitably workable on a large scale. Mr. Scott therefore had relinquished his concession by the end of 1963. But it was agreed that further work would be done to assist Basutoland Factory Estates Development Ltd., a company nominated by the Basutoland Government to investigate and exploit diamond deposits profitably workable on a small scale.[3]

BECHUANALAND

Considerable mineral exploration by large companies was in progress in Bechuanaland in 1963, but as for several previous years, production was limited to chrysotile asbestos, manganese ore, and gold with minor associated silver. Mineral exports were valued at R368,397, of which asbestos contributed 59.4 percent and manganese ore 39.6 percent. Gold and silver exports amounted to 142 ounces and 21 ounces. The 1963 export value compares with R616,129 in 1961, when minerals contributed about 10 percent of the total value of exports.

COMMODITY REVIEW

METALS

Copper.—In its report for the year ended June 30, 1963, Rhodesian Selection Trust, Ltd. (RST), reported copper discoveries in Bechuanaland, where RST has been exploring for some years. At one locality ore was found that could be significant if persistent. Exploration was proceeding, but it was clear that considerable work including diamond drilling would be necessary to determine the importance of the discovery. RST exploration in Bechuanaland was being concentrated on the copper area.

Manganese.—Early in 1963 the target output of Bamalete Manganese (Pty.), Ltd., about 18 kilometers (11 miles) north of Lobasti and about one-half mile from the Mafeking-Rhodesia railroad, was 5,000 tons of manganese ore per month. The capacity of the crushing and screening plant was about 15,000 tons per month. The ore is crushed to about 1½ inches, the size acceptable to Japanese buyers.[4]

NONMETALS

Asbestos.—The Bechuanaland production of chrysotile asbestos comes from the Moshaneng mine about 13 kilometers west of Kanye, operated by Marlime Chrysotile Asbestos Corp., Ltd., a subsidiary of Marble Lime and Associated Industries, Ltd., of Johannesburg. The ore contains about 2 percent asbestos. The mine has a large modern mill with capacity greater than present production.

Brines.—For more than 3 years Rhodesian Selection Trust, Ltd., has conducted, through a subsidiary, extensive investigations of brines found beneath the surface of Sua Salt Pan adjacent to the Bamang-

[4] South African Mining & Engineering Journal. Jan. 25, 1963, p. 192.

Digitized by Google

wato tribal area. The work was expected to be completed before the end of June 1964, when the economic possiblities of the salts would be assessed.

Diamonds.—Kimberlitic Searches, Ltd., prospected for diamond on behalf of De Beers Consolidated Mines, Ltd. A large area was covered but nothing of economic value was found, according to the Annual Report of De Beers for 1963. Interest in diamond possibilities in Bechuanaland was first aroused in 1959 when Consolidated African Selection Trust, Ltd., found small diamonds in rubble accumulations near Foley and elsewhere.

MINERAL FUELS

While Bechuanaland produces no coal, it has extensive favorably situated coalfields that probably will be exploited eventually. The known coals are low- to medium-rank bituminous coal with no coking properties. There are three fields of which Mamabule, between Debeeti and Mamabule, has the largest proven reserves. Mamabule has two seams; one investigated in an area of 66 square kilometers contains 163 million tons of coal; the other contains 245 million tons in an area of 50 square kilometers. The maximum depth from the surface to unweathered coal appears to be about 27 meters.

SWAZILAND

Mineral industry has had a major role in the Swaziland economy for many years and is becoming increasingly important. In 1961 the industry contributed 40 percent of the total value of exports, and by 1965 its contribution may be of the order of 50 percent. Mineral exports were valued at R4.1 million in 1963 and in 1959–63 averaged R4.8 million with no sharp fluctuations from year to year. While some 10 minerals generally were mined during the period, asbestos each year contributed more than 90 percent of total value. Large-scale iron mining to begin in 1964 is expected to increase the value of the Swaziland mineral exports by 100 percent or more. The new operation also will provide very substantial additional employment, statistics for which were as follows for Swaziland mining industry in 1962:[5]

	Skilled labor	*Unskilled labor*
Persons employed, monthly average	173	1,737
Earnings, year	R437,814	R342,202
Food furnished, value	--------	R116,019

COMMODITY REVIEW

METALS

Gold.—Prospecting by diamond drilling was in progress at the dormant Daisy mine in the Hoho area, Pigg's Peak District. Two holes had returned very encouraging results and three more holes were in progress. The mine, dormant since 1905, was abandoned when sulfide ore was encountered. At the surface the strike length of the vein is about 460 meters. If the ore persists in depth, it is possible that a large gold mine can be established.

Iron Ore.—Open-pit mining by Swaziland Iron Ore Development Co., Ltd. (SIOD), of the rich Ngwenya deposit at Bomvu Ridge north of Mbabane was expected to begin in 1964. SIOD is administered by Anglo American Corp. of South Africa, Ltd. Proven reserves of direct shipping ore in the deposit are about 42.6 million metric tons averaging about 62 percent iron. SIOD has undertaken to deliver about 813,000 metric tons in the 12 months immediately following completion of a railroad built specifically for the project and about 1.2 million metric tons annually thereafter for 9 years. The buyer is a Japanese consortium headed by Yawata Iron & Steel Co. and Fuji Iron & Steel Co., Ltd. The consortium agreed to take approximately 12 million tons of ore at R7 per ton or a little less, depending on iron content of each shipment. The price is free on board, port of Lourenco Marques, to which the ore will be shipped by rail. Actual shipments are expected to average about 1.2 million tons a year for 10 years, yielding around R84 million (US$117.6 million).

According to one source,[6] the cost of handling the ore at Lourenco Marques will be somewhat less than the cost of mining it. Rail freight will be about three times mining costs, and total cost to the buyers will be more than ten times mining costs, according to the source.

Besides preparation of the mine for production and construction of some 224 kilometers of railroad through rugged country to the Mozambique border, the SIOD project comprises railroad construc-

[6] Financial Mail, Johannesburg. Swaziland Supplement. Nov. 2, 1962, p. 31.

Digitized by Google

tion on the Mozambique side of the border, constructing ore loading facilities and deepening the harbor at Lourenco Marques, and building large ore carriers. In all, the capital involved reportedly was around the equivalent of US$70 million.[7]

Tin.—A mill was under construction to treat tin-bearing pegmatite near Mbabane. Proved ore reserves were reported as 50,000 tons, containing 185 long tons of tin and averaging 0.37 percent tin.[8]

NONMETALS

Asbestos.—The Havelock mine of New Amianthus Mines (Pty.), Ltd., controlled by Turner and Newall, Ltd. of the United Kingdom, furnishes the Swaziland chrysotile asbestos. Its mill was modernized in 1962 and early in 1963 a 1,200-foot vertical shaft was approaching completion. The shaft will make available many millions of tons of ore that is contained in a safety pillar of the old inclined shaft and therefore could not be extracted. Production from the mine can be sustained for many years at the present rate; 30,255 metric tons of asbestos, valued at R4,030,771, was produced in 1963.[9] In 1961 and 1962 Havelock explored its concession 41 in detail, and sank a shaft through which development was undertaken to test the western extension of the Havelock serpentine. Results were not divulged.

Havelock is one of the major sources of spinning grade chrysotile asbestos in the world. The ore body has a strike length of 1,372 meters and in width ranges from 18 to 107 meters, averaging about 45 meters. The asbestos occurs as a stock work of cross-fiber seams and comprises between 3 and 4 percent of the ore body. The average length of the fibers is between one-half and three-quarters inch.[10]

Barite.—Early in 1963 the barite reserves of Swaziland Barytes, Ltd., the only producer, were reported as 1,080,000 tons.[11] Output nevertheless has been small because of the limited market in the Republic of South Africa, where production also exists. It was hoped that completion of the Swaziland railroad to the port of Lourenco Marques would make possible sales to the Middle East oilfields.

Kaolin.—Bulk tests on kaolin from a large deposit in the south of Swaziland showed that the material was of top quality, being suitable for use both in all branches of ceramic industry and as a filler. The deposit was first exploited in 1961, and in 1963 output was 2,007 metric tons. The development is important to the Republic of South Africa, where no extensive deposits of high-grade kaolin are known.[12]

MINERAL FUELS

Central Mining and Finance was reported to be planning to open its Mpaka colliery on Crown Mineral area 9 late in 1964 to supply coal to the new railroad, two sugar mills, other Swaziland industries, and for household use. Swaziland has important reserves both of anthracite and bituminous coals.

The Mineral Industry of Cameroon

By Thomas G. Murdock [1]

THE DOMESTIC MINING industry of the Federal Republic of Cameroon, is relatively small; mining during recent years has been limited to small quantities of gold and tin. The most important activity is aluminum production, using imported alumina; the country possesses the only facility of this kind in Africa. In 1963 aluminum output set a record high, with 1 percent of world production. This achievement was the most significant event of the year. Gold production was more than twice that of 1962, but it was still below that of a decade earlier. There was no revival of the former rutile and cement production. The extensive bauxite and iron ore deposits remained undeveloped, and petroleum exploration had not revealed economic occurrences.

In 1962 the gross national product (GNP) was CFAF91,140 million (US$372 million); [2] the mineral production, exclusive of building materials, had an estimated value of CFAF5,447 million, 6 percent of the GNP. For 1963 the estimated value rose to CFAF5,580 million, hardly sufficient to affect the share contributed to the GNP.

Data on employment in the mining industry in 1963 are not available. In 1960 the aluminum plant labor force consisted of 600 Cameroon workers and 100 European technicians, foremen, and training personnel. With the increased production since then, employment of workers undoubtedly has increased; however, it is believed that the Europeans force has declined appreciably as local personnel have advanced in technical ability. Regardless of the actual number employed in the minerals sector, those employed remained only a small part of the 4.4 million estimated 1963 total population.

GOVERNMENT POLICIES AND PROGRAMS

During 1963, Cameroon made slow progress under the 5-year plan covering 1961–65, which continued the work of two earlier plans. In the current plan, investment was projected to decline while per capita incomes were expected to rise. Expectations were that there would be a sharp decline in investment in the private sector of the economy. On the other hand, investment in economic infrastructure, such as railways, highways, and communications, was expected to increase substantially. Continuing increases in outlays for social equipment, such as schools and hospitals, were also expected.

Digitized by Google

In view of its great need for investment funds, the Government of Cameroon continued to actively encourage the investment of foreign capital. The investment code, adopted June 11, 1960, provided substantial incentives for this purpose. No new legislation directly applicable to the mining industry was enacted; however, a new mining code was being drafted at yearend. A new agreement between the government and the aluminum producer was signed late in 1962.

The first Cameroonian Federal Chamber of Commerce, Industry and Mines was formally inaugurated on October 9, in Douala. The new chamber was to represent private enterprise, bring about close cooperation between all sectors of the economy, and fully exploit the economic and commercial agreements which Cameroon had signed with various countries.

On March 2, the president of the Cameroons ratified the various economic, technical, commercial, and cultural agreements signed with Poland, Yugoslavia, Greece, Taiwan, Lebanon, and Israel during the visits, late in 1962, of two Cameroonian missions to those countries and others in Europe, the Far East, and the Middle East. A Swedish company, Sueco-Camerunia Aktiebolag, announced that it would inaugurate a program of mineral exploration in west Cameroon near the end of 1963.

SOURCE MATERIAL

Data on production and 1963 developments are almost entirely from dispatches of the U.S. Embassy in Yaoundé. Some background information was provided by a French publication.[3] Foreign Trade statistics are inadequate for a complete, detailed analysis; some information has been provided by publications of the French Government and the European Economic Community (EEC).

PRODUCTION

The most pronounced trend for 1959–63 was a continual annual increase in aluminum output. Gold production fluctuated considerably; the 1963 level was considerably above that of 1959 but below that of the early 1950's. Tin showed little change, except for 1962 when the operations changed ownership. Cameroon apparently produced most of its requirements of construction materials; however, no quantitative data are available. Indications are that 1963 construction activities were slightly below those of 1962; building permits issued in Yaoundé, the capital, and Douala, the port city, declined from 56,800 to 50,000 square meters.

[1] In addition, building materials other than cement and lime were produced, but no quantitative data are available.
[2] Production ceased and plant closed.

TRADE

Data available on metals and minerals traded by Cameroon are limited to the major items. In 1962 the exports of primary metals of domestic origin were valued at CFAF5,300 million (aluminum, CFAF 5,294 million, and gold, CFAF6 million). In addition, exports of scrap metals were made; EEC recipient countries reported combined imports of these from Cameroon worth CFAF48 million (ferrous scrap, CFAF25 million and nonferrous scrap, CFAF23 million). The 1962 exports of aluminum and gold comprised 21 percent of all exports, on the basis of value (20 percent in 1961, when exports of these commodities were worth CFAF4,803 million). The 1962 major metal and mineral imports were valued at CFAF5,214, comprising 21 percent of all imports (CFAF4,645 and 20 percent in 1961). In 1962 the major metal and mineral imports, including manufactured metals not identified separately, were alumina, CFAF1,470 million; iron and steel, CFAF648 million; other nonferrous metals, CFAF1,179 million; cement and lime, CFAF324 million; salt, CFAF120 million; and petroleum refinery products, CFAF1,473 million. In addition there were small quantities of coal and coke; exports of these by EEC to Cameroon were valued by the exporting countries at CFAF2 million.

Information available does not identify adequately Cameroon's partners in the 1962 mineral trade. France undoubtedly ranked first, as reflected by that country's share in total trade (60 percent of all exports and 55 percent of all imports). Receipts of exports from Cameroon by EEC, of which Cameroon is an associate member, totaled CFAF5,173 million in 1962 for aluminum and scrap metal. Exports of metals and minerals (exclusive of metal manufactures) to Cameroon by EEC were worth CFAF1,178 million; Guinea supplied all of the alumina, and Netherland Antilles supplied CFAF650 million worth of petroleum refinery products. Trade in metals and minerals with the United States was small; this country supplied petroleum refinery products valued at CFAF100 million and metals and metal products worth CFAF37 million. U.S. imports of Cameroon aluminum were valued at CFAF9 million.

Through September the 1963 exports of major metal and mineral commodities enumerated for 1962 were at an annual rate of CFAF-4,715 million; the corresponding value of imports was CFAF5,051 million.

COMMODITY REVIEW

METALS

Aluminum.—Compagnie Cameroonaise d'Aluminum Péchiney-Ugine (ALUCAM), a company owned and managed by a French aluminum and chemical interest with a 3-percent interest held by the Cameroon Government, continued the production in its plant at Edéa on the Sanaga River, at a level slightly above that of 1962. Operations began in February 1957, and the plant has gradually increased output; however, no significant rise above the 1962 level was possible because of the seasonal drop in the flow of the Sanaga, which requires cutting out a portion of the plant when available hydroelectric power declines. This situation resulted in a range of monthly production in 1963 of from 2,647 metric tons in April to 5,870 in August, and an average

Digitized by Google

of 4,410. To overcome this water shortage, the construction of a storage dam far up the river had been proposed; in September it was reported that the studies of the most suitable place to build this dam were nearing completion and construction would begin within a few months. Two years would be required to complete the facility.

Power for the aluminum plant was supplied by Société Énergie Électrique du Cameroon, operators of the Edéa hydroelectric plant; in the first half of the year 472 million kilowatt-hours was consumed, or 18,709 kilowatt-hours per ton of aluminum produced, and average cost per kilowatt-hour was CFAF0.50. The alumina again came entirely from Guinea, and imports were probably about 91,000 tons.

ALUCAM operated under the long-term agreement that had been decreed on November 29, 1962. This agreement provided for continuation of the previous favorable customs and tax provisions for 20 years, essentially without change. The company agreed to remit to the government 60 percent of the foreign exchange derived from aluminum sales outside the franc zone. This figure, however, was to be computed from the value added at Edéa to the alumina, imported duty-free, rather than the f.o.b. price of the aluminum at Douala. A new corporation (CAMAL) was formed to control these sales and this division of foreign exchange. It was further agreed that the government may commit up to one-third of ALUCAM's production in concluding agreements with other countries, and no aluminum is to be stockpiled while the government looks for buyers. Instead, the Government will exercise its right by requesting delivery from current production once all conditions of sale have been met. ALUCAM also agreed to increase the proportion of Cameroon citizens in the upper echelons of its management, to pay higher rates for the additional power expected to be available after completion of the storage dam on the Sanaga, and to take part in development studies of the feasibility of opening up domestic bauxite deposits.

In 1960, Société Cameroonaise de Transformation de l'Aluminum was founded by ALUCAM, other French interests, and several leading commercial firms of Cameroon. This company installed rolling facilities in a plant adjacent to the ALUCAM plant, for the production of corrugated sheets for roofing and siding. Plans were initially to use imported coils and later to start from Edéa ingots. In 1962 production began with 400 metric tons of corrugated sheets; while data on 1963 output are not available, it was expected that 800 tons would be produced. Neighboring franc zone countries were expected to provide the market.

Through September exports of aluminum were at the annual rate of 44,925 metric tons, 12 percent below the 1962 total. U.S. 1963 imports from Cameroon were 2,585 metric tons (100 tons in 1962).

Bauxite.—No new developments toward the economic utilization of Cameroon bauxites were reported other than further investigations of the economics involved. Latest figures on bauxite reserves are 40 million metric tons containing 45 percent alumina and 2 percent silica after screening for the Fongo-Tongo deposit in Menoua Department, and over 1 million tons with 43 percent alumina and 3.4 percent silica for the Minim-Martap and Ngaoundal deposits in Adamaoua. The location of the latter deposits, over 1,100 kilometers from the sea and

Digitized by Google

almost as far from Edéa, at least has held back their development pending the completion of the proposed Transcameroon Railway, bids for which were to be opened at yearend. With the comparatively small alumina requirements of the Edéa plant, over half the output of even a minimum-sized alumina plant would have to be exported; with the expected high production cost this alumina would not be competitive on the export markets. Early forecasts have been that only by 1975–80 could a development be economically feasible. ALUCAM is to participate in further investigations, with other interested parties, and reportedly is to purchase any alumina produced domestically, on a preferential basis.

Gold.—The gold production continued to come mainly from the Betare-Oya region, where tributers work within the permit of Compagnie Minière du Cameroon and sell the gold to the company. The substantial increase probably resulted from an improved control over the mining, although richer ground worked or more workers engaged could have been responsible. Exports through September were at the annual rate of 1,929 ounces.

Tin.—Following the 1962 takeover of operations at the Mayo Darle tin mine by a new operator, Société de Fibre et Mécanique of Douala, production rose to approximately the previous level. Indications are that the increased output came mainly from reworking old tailings. Production was 91 long tons of concentrates containing approximately 66 percent tin.

NONMETALS

Cement.—In September, plans were announced for the construction of two cement plants. These were to be established under the provisions of a technical cooperation agreement between the Cameroon Government and West Germany. Specific locations of the plants were not given, but a 75,000-ton-per-year plant is to be built in the north and one of 30,000-ton capacity in the south.

MINERAL FUELS

Petroleum.—Société de Recherches et d'Exploitation des Pétroles au Cameroon (SEREPCA), a predominantly French oil company capitalized at CFAF4,700 million in which the Cameroon Government holds 10.7 percent of capital, continued intermittent exploration. Since SEREPCA was created in 1951, it has put down 47 wells totaling approximately 58 kilometers in depth, within a 32-kilometer radius of Douala. Two small oil pools and two minor gas deposits were discovered, but no commercial production has resulted. Reportedly, 350 to 400 million cubic meters of gas could be used by the small industries in the area; however pending additional demand, production has not been started. Expectations at yearend were that an extensive series of seismic tests would be effected in 1964 and more drilling might follow in 1965.

During the year agreement in principle was reached for the Cameroon Government to participate with those of the Central African Republic, Chad, Congo (Brazzaville), and Gabon in the construction of a 700,000-metric-ton-per-year refinery at Port Gentil, Gabon.

Digitized by Google

On September 18, the Cameroon Investment Committee approved the application of Azienda Generale Italiana Petroli, the marketing agency of the Italian Government Ente Nazionale Idrocarburi, for benefits under the investment code. Approval was given for exemption from duties and taxes on plant, machinery, and raw materials imported into the country. Exemption from taxes on industrial and commercial profits during the first 5 years of operation was denied.

The Mineral Industry of the Central African Republic

By Thomas G. Murdock [1]

THE CENTRAL AFRICAN REPUBLIC, formerly the territory of Oubangui-Chari of French Equatorial Africa, has a relatively small mineral industry. Production in 1963 was limited to a small quantity of diamond (1.1 percent of the world total) and a few ounces of gold recovered as a byproduct of diamond mining. However, the industry is important to the economy of the landlocked country, and in 1963 diamond exports comprised about 42 percent of all exports on the basis of value. In 1962 the gross national product (GNP) was CFAF12,495 million (US$51 million); [2] the mineral production had an estimated value of CFAF1,084 million, 9 percent of the GNP. With the greatly expanded diamond production, the GNP increased to CFAF2,501 million in 1963, with a consequent rise in the share contributed by mining.

An alltime high in diamond production was reached in 1963. A new organization to increase further production of diamond through Government participation in mining and maintaining the output in the legitimate trade, through a closer control of the production and marketing, was established. Exploration of occurrences of other minerals also gave promise of some possible diversification of the industry.

Data on the total employment in mining are not available. An estimated 15,000 individual entrepreneurs were engaged in mining for sale to itinerant buyers at yearend. Employment by the established mining companies probably was down to about 5,000 following the decreased production since 1956, when 9,850 were working. Thus, indications are that about 20,000 workmen are engaged in mining. This is only a small part of the economically active labor force which was estimated in 1960 to be 35 percent of the total population; the population was estimated at 1.3 million in 1963.

A U.S. company continued its participation in two of the diamond-mining companies during 1963 and bought additional diamonds in the country. Announcement was made of its participation in setting up a cutting establishment.

GOVERNMENT POLICIES AND PROGRAMS

Following the adoption of a new mining code in 1961, no specific legislation relating to mining in general was recorded. Mining was,

[1] Mining engineer, Division of International Activities.

[2] African Financial Community (CFA) francs are used in the country. The exchange rate is US$1=CFAF245 (CFAF1=US$0.0040816).

Digitized by Google

however, encouraged by certain provisions of the new investment code, promulgated as law No. 62355 on February 19, 1963. New activities are to be exempted from income taxes for an initial period of 5 years; for a subsequent 3-year period, a reduced rate may be granted to certain enterprises. Several measures applying especially to diamond mining were taken during the year, to change the method of Government participation and to more effectively control the individual miners. The private mining companies' status was not altered.

Following a reorganization and the receipt of needed equipment, the Mining and Geological Service carried out the investigative program scheduled for 1963. Prospecting was undertaken by engineers placed at the Service's disposal through the Cooperation Française and assisted by Africans trained under a program instituted by the Service.

SOURCE MATERIAL

Data on production and 1963 developments are from dispatches of the U.S. Embassy in Bangui, effectively supplemented by a comprehensive coverage in the technical press.[3] Trade data are from the Union Douanière Équatoriale.

PRODUCTION

The production trend for 1959–63 reflected rather closely the changed structure of the industry. Gold output, limited to that recovered as a byproduct of diamond mining, has declined sharply since 1960 and reached a new low in 1963. Following the inauguration of diamond mining by individual miners to supplement the operations of the established companies and the activities of local buying offices established in early 1961, production rose sharply to the high in 1963 when the individual miners produced 82 percent of the total.

TABLE 1.—Production of metals and minerals

Commodity [1]	1959	1960	1961	1962	1963

Total.....do....	86,600	69,641	111,484	265,417	402,364

[1] In addition, building materials are produced but no quantitative data are available.

TRADE

In 1962 the total value of metal and mineral imports was CFAF654 million, 11 percent of all imports, compared with CFAF633 million and 12 percent in 1961. The 1962 import value by categories follows: Metals, CFAF234 million; nonmetals, CFAF145 million; and mineral

[3] Mining Journal (London). Central African Republic-Record Diamond Output in 1963. V. 262, No. 6719, May 29, 1964, p. 423.

Digitized by Google

fuels, CFAF275 million. The exports were valued at CFAF790 million (CFAF371 million in 1961) and comprised 22 percent of all exports (11 percent in 1961); they consisted of diamonds (valued at about CFAF715 million), petroleum refinery products of nondomestic origin (valued at about CFAF75 million), and gold, lime, and unidentified materials (together valued at less than CFAF500,000).

France continued to be the country's leading supplier of metals and minerals, with 40 percent of the total; the European Common Market, of which the Central African Republic is an associate member, supplied 51 percent in the aggregate. Netherlands Antilles and Venezuela, main suppliers of petroleum refinery products, ranked second and third, respectively, followed by the United States which also supplied these commodities and accounted for 9 percent of all metal and mineral imports. These items comprised 22 percent of all imports from the United States. The United States ranked first as a recipient of metal and mineral exports, with 36 percent, followed by France (18 percent) and Israel (17 percent). Mineral exports to the United States, exclusive of diamond, comprised 61 percent of total Central African Republic exports to that destination.

Assuming that in 1963 metal and mineral imports accounted for 11 percent of all imports, as they did in 1962, they would have had a value of CFAF717 million. Diamond exports in 1963 were valued by preliminary figures at CFAF2,258 million, or 216 percent above those of 1962.

COMMODITY REVIEW

METALS

Gold.—The small gold production continued to be obtained as a by-product of diamond mining, with the combined output of the companies amounting to 35 ounces and that of the individual miners to 41 ounces. The Mining and Geological Service continued investigations of gold deposits in the eastern part of the country, between Alindao and Kembe.

Iron Ore.—At Bogin, two beds of iron ore, grading 68 percent iron over a length of 500 meters, were explored by the Mining and Geological Service. The beds averaged 6 to 8.5 meters thick and 10 meters deep. Plans were made to exploit the deposits at the rate of 7,000 metric tons per year.

Tin.—Occurrences of cassiterite at Ippy, Bria, and Yalinga were scheduled for investigation, and arrangements were made for a West German expert to lend technical assistance in the project during 1964.

Uranium.—A permit for prospecting for uranium was granted in the Bengassou region to the French Atomic Energy Commission, which started work in December on an aerial scintillometer survey of 5,200 square kilometers.

NONMETALS

Diamond.—Of the 1963 record high diamond production, 73,960 carats were produced by the mining companies (61,379 carats in 1962); 58,331 carats came from the western region centered on Berberati and Carnot, and 15,629 carats came from the eastern region near Ouadda. Most of the output, however, was mined by individual African diggers and purchased by non-African buyers; of the 328,404 carats obtained in this way (265,417 carats in 1962), 64 percent was bought in Bangui, 33 percent in Carnot, and 3 percent in Bria. Indications were that, as in former years, the gem variety constituted 30 percent of the total on the basis of weight and 70 percent were industrials. On the basis

Digitized by Google

of value, however, these proportions were 60 percent and 40 percent, respectively.

Data on 1963 production of individual companies are not available. In 1961, when the output of the individual miners was 57 percent of the total, the leading company producer was Compagnie Centraficaine de Mines, an affiliate of Diamond Distributors, Inc., of New York, with 20 percent, from operations in the western region. Another affiliate of this U.S. organization, Compagnie Diamantifière du Dar Challa, active in the east, contributed 2 percent. Other producers, all controlled by French interests, in 1961 were Société Minière de l'Est Oubangui, at Yalinga (9 percent); Société Africaine de Mines, at Ouandjia (8 percent); Société Minière de Carnot, at Carnot (3 percent); and Société Anonyme de Recherches et d'Exploitations Minières, at Ouadda-Bria (1 percent).

Through November exports were at the annual rate of 364,000 carats. Preliminary data indicate that Israel was consigned 196,500 carats in the entire year; practically all of the remainder went to the United States. Total diamond exports of the country through 1963 were about 2.7 million carats; all were produced from alluvial deposits.

A number of important developments in the diamond industry took place towards the end of 1963. On December 19, the National Assembly passed a law to establish Société Nationale de Recherches et d'Exploitations Minières (SINAREX), a diamond-mining firm owned by the State. SINAREX was to establish several small diamond-mining centers in the southwestern region of the Republic within the next 2 years. It was expected that each center will cost CFAF40 million. Funds are to be provided by the National Development Bank and are to be repaid in 10 years. Prospecting will be undertaken by the Mining and Geological Service. Around each center, manned with 2 or 3 French mining engineers and 15 to 30 Central African laborers, the Government expects to build small villages with a minimum of public facilities, together with retail stores and licensed buying offices. It was hoped to attract to these centers most of the individual diggers, scattered throughout the region, whose operations were almost impossible to control. The diggers will be free to use the facilities provided and will be expected to sell their stones to the licensed buying offices, which, in turn will sell their lots to the major European- or U.S.-operated buying offices in Bangui. The Government will sell its own production directly to buying offices in Bangui.

Operations of privately owned diamond-mining companies were not affected by the establishment of SINAREX, which appeared to be motivated principally by the Government's desire to increase diamond production and to rid the country of the estimated 5,000 to 6,000 West African middlemen, of whom only about 150 are licensed.

The Israel-Central African Republic (ICAD) diamond export monopoly was dissolved on December 31. Henceforth each buying office will export its own lots directly, the full 10-percent export tax being remitted to the Government, which received slightly less than half this figure under the profit-sharing agreement with ICAD. Pituach Centrafricaine des Diamants, a subsidiary of Pituach-Israel, was formed on December 14 to engage in the buying, export, and sale

Digitized by Google

of rough diamonds. It will compete on equal terms with other privately owned diamond-buying offices in Bangui.

To combat the illicit trade in precious stones outside the Central African Republic, the Mining Brigade, attached to the Mining and Geological Service, was being organized. Recruitment of 40 agents was envisaged, when the necessary financial arrangements were completed. Announcement was made of plans for the establishment of a diamond-cutting industry in 1964; this will be by an association of the Government and Diamond Distributors, Inc.

Other.—Nonmetals exploration activities by the Mining and Geological Service included the exploration of brick clay deposits resulting in quantities sufficient for exploitation at the proposed rate of 12,000 tons per year, an investigation of granite deposits near Bouar and preparation of plans for setting up sawing and polishing facilities, and investigations of deposits of limestone at Bobassa, south of Bangui, where seasonal extraction is under consideration in connection with a project for the manufacture of 20,000 tons of cement per year.

MINERAL FUELS

The Central African Republic participated with its partners in the Equatorial Customs (Chad, Congo-Brazzaville, and Gabon) and nearby Cameroon in the successful negotiations for the establishment of the petroleum refinery at Port Gentil, Gabon, to be in operation by 1966 and to have an annual capacity of 700,000 metric tons.

The Mineral Industry of Chad

By Thomas G. Murdock [1]

THE REPUBLIC OF CHAD, formerly the territory of Chad of French Equatorial Africa, is a mineral-poor country dependent upon its agricultural resources for economic development. Mineral production has been limited to a small amount of natron and an unrecorded quantity of building materials. With the possible exception of oil, there seems to be little prospect of any significant investment in or exploitation of minerals in Chad. As an importer of minerals and metals in 1962, the country ranked high in comparison with its partners in the Equatorial Customs Union (ECU), accounting for 31 percent of the total value for these commodities; 180 percent and 40 percent more than the Central African Republic, and Gabon, respectively; and only 14 percent below the Republic of Congo (Brazzaville).

The 1962 gross national product (GNP) was CFAF29,616 million (US$120 million),[2] the highest of any ECU country. Natron production was valued at an estimated CFAF222 million, less than 1 percent of the GNP. The value of building-materials production, if data were available, would not alter significantly this small contribution.

Data on employment in natron extraction are not available. It is a tribal activity and is an intermittent operation following the annual rainy season (June to September); workers engaged are from the Bornou, Kanembou, Kotoko, and Boudouma tribes, probably numbering several hundred at the height of annual activity. They undoubtedly constitute an insignificant part of the economically active group, comprising less than 50 percent of the 3.1 million population, considering that more than 90 percent of this group is engaged in agricultural pursuits.

The year 1963 saw no changes in the mineral position of Chad other than the 23-percent increase in mineral imports. Natron mining continued at the level of the preceding year, and although in September rumors of a substantial oil find in northeastern Chad caused some optimism, later conclusions were that this was premature.

GOVERNMENT POLICIES AND PROGRAMS

No new mining legislation was reported in 1963. Likewise no amendments to the Chadian petroleum code adopted on February 3,

[1] Mining engineer, Division of International Activities.
[2] African Financial Community (CFA) francs are used in Chad. The official exchange rate used is US$1=CFAF246.8 (CFAF1=US$0.004052).

Digitized by Google

1962, were reported. A comprehensive investment law was promulgated in August 1963, which was liberal in content and aimed to encourage investment in industries beneficial to the development of Chad. Following the enactment of this law negotiations were begun on an investment guarantee agreement with the United States but at yearend this was still pending.

During the year an interim development plan for 1964–65 was under preparation. This plan placed emphasis on the construction and improvement of all-weather roads within Chad, expanding educational and technical-training facilities and personnel and improving agricultural production. Much of the development depended on aid from France and other members of the European Common Market, of which Chad is an associate member. In May, the French aid agency made a grant of CFAF78.6 million to the Cameroon-Chad Joint Railroad Commission for preliminary technical studies regarding extension of the Trans-Cameroonian Railroad from Ngaoundere, Cameroon, to Fort Archambault in southern Chad. The studies were to last 2 years and began previous to actual granting of funds. On July 10, 1963, Chad became a member of the International Bank for Reconstruction and Development and the International Monetary Fund. Plans for the participation of Chad in financing a cemet plant in northern Cameroon were announced; installation of this facility was scheduled for 1965, and expectations were that Chad would take 15,000 metric tons of the annual production.

SOURCE MATERIAL

Data are almost exclusively from dispatches of the U.S. Embassy in Fort Lamy, particularly an annual summary prepared especially for this review.[3] Trade data are from the Union Douanière Équatoriale.

PRODUCTION

Reported production of minerals in Chad has consisted only of natron; output in 1959 was only 3,000 metric tons, rising in 1960 to 6,000 tons, and again doubling to 12,000 tons in 1961. An increased local demand and expanded exports permitted substantial subsequent growth, and for 1962–63 production was placed at 25,000 tons. Production of building materials is not recorded; although no quantitative data are available, indications are that except for cement, some varieties of clays, and lime, Chad is self sufficient, and there has been some growth in production in the 1959–63 period.

TRADE

In 1962 the total value of metals and minerals exports was CFAF198 million, 4.7 percent of all exports, compared with CFAF65 million and 1.2 percent the previous year. The 1962 exports consisted of scrap copper (CFAF1 million), natron and other nonmetals (CFAF36 mil-

[3] Smith, M. B. Information on Chad for Minerals Yearbook. U.S. Embassy, Fort Lamy, Chad. State Dept. Airgram A–157, Feb. 29, 1964, 4 pp.

Digitized by Google

lion), and petroleum refinery products of nondomestic origin (CFAF 161 million). The 1962 metals and minerals imports were valued at CFAF1,833 million, 24 percent of all imports (CFAF1,488 and 24 percent in 1961). The import value by categories was: Metals, CFAF317 million; nonmetals, CFAF436 million; and mineral fuels, CFAF1,080 million).

Of the 1962 exports of metals and minerals, deliveries to aviation bunkers accounted for 78 percent; Nigeria with 15 percent and Cameroon with 6 percent received practically all of the remainder. As a supplier of petroleum refinery products, Netherlands Antilles was the principal source, with 39 percent of all metal and mineral imports, followed by France (27 percent) and the United States (9 percent). The European Common Market as a whole supplied 42 percent of these. Imports from the United States, almost all of petroleum refinery products, comprised 52 percent of all imports from that country.

In 1963 total exports rose to CFAF5,605 million and if metals and minerals comprised 4.7 percent as they did in 1962, their value would have been CFAF263 million. Natron exports, were at approximately the same level as in 1962, however, bunker sales of aviation fuels may have shown a substantial increase from 1962. Total imports in 1963 were approximately the same as in 1962, however, imports of refined petroleum products rose to CFAF1,129 million and if other mineral and metal imports rose in the same proportion the total for all would have been CFAF1,915 million.

COMMODITY REVIEW

METALS

No new developments were reported for the only recorded metal occurrences in Chad of columbite, tin, and tungsten in the Tibesti region. Except for 22 tons of tungsten ore obtained during the 1957–58 exploration of the deposits, there has been no production and an economic exploitation has remained problematic.

NONMETALS

The Chadian natron, a mixture of sodium carbonates and chloride, is found in substantial quantity in and around Lake Chad, 110 kilometers north of Fort Lamy. Smaller quantities occur in Borkou and Ennedi but because of geographical considerations these latter sources remained unexploited. The center of the Chadian natron industry is Bol, on the northeastern shore of Lake Chad. When the lake waters

Digitized by Google

begin to dry up after the annual rainy seasons, tribal workers excavate along the still-wet shores to a depth of about 1.5 meters, where the natron is encountered and extracted in pieces averaging 60 kilograms in weight and 15 centimeters in thickness. After extraction the natron is placed on straw mats and dried in the sun for 2 or 3 days. When dry it is cut into rectangular or tombstone-shaped blocks of about 30 kilograms weight and carried to Bol by camels. There it is moved by barges across Lake Chad and up the Chari River to Fort Lamy for sale to local Moslem merchants. The natron is then retailed in the local markets or exported, mainly to Nigeria. The Chadian Customs in 1963 established a suboffice in Bol to permit exports of natron to move directly from Bol to northern Nigeria. Natron is widely used by Africans as a household seasoning, a remedy for minor ailments, and a flavoring for chewing tobacco. Chadian women mix natron with ashes of burnt wheat stalks to make soap; Chadian herders give it to their cattle as preventive medicine; and it is also used in tanning leather. Preliminary information placed the 1963 exports at 4,000 tons, about the 1962 level. In view of the relatively minor role in the total Chadian economy, the government has taken no major steps to encourage its production.

MINERAL FUELS

Petroleum exploration was continued in 1963 by a single company, the French Société de Participations Pétrolières (PETROPAR), holding exclusive exploration and exploitation rights in two areas. Following minor discoveries of noncommercial value in the late 1950's in the Tibesti Mountains near Baidai, PETROPAR gave up the search there but retained all rights, confining subsequent work to the Tekro area in northeastern Chad. Rumors of a major oil find in the Tekro area circulated around Fort Lamy in late 1963. It was known that PETROPAR had brought in European oil geologists to work in the Tekro region, and reports were that 4 drill rigs had been shipped from Douala, Cameroon, to Tekro. By yearend, however, nothing further had been heard regarding the discovery, and there was no confirmation of the discovery by French or Chadian officials. Even if substantial reserves of oil were found in northern Chad, there would remain the problem of transport; considering this and the present supply position, it is doubtful that a commercial exploitation would follow in the near future.

Total imports of petroleum refinery products in 1963 were 34,800 metric tons, 5 percent below those of 1962. The country continued to depend almost exclusively for energy on these imports. Preliminary general studies of possible hydroelectric development at Gauthiot Falls in the Mayo Kebbi area, were continued in 1963. Appreciably increased imports of distillate fuel oil in 1962 over those of 1961 reflected the greater generation of power by diesel plants in the country. Plans were announced for electrification of Fort Archambault in the near future; it would cost CFAF300 million and would increase fuel oil requirements.[4]

The Mineral Industry of the Republic of Congo (Brazzaville)

By Thomas G. Murdock [1]

THE REPUBLIC OF CONGO, formerly the territory of Moyen Congo of French Equatorial Africa, has a mineral industry which thus far has been of little importance to the world mineral economy. Production in 1963 consisted of small quantities of gold and nonferrous metals and an insignificant volume of crude petroleum from a single field. However, the country's recorded metals and mineral exports continued to be enhanced by the inclusion of a large quantity of diamond believed to have originated in the adjacent Republic of the Congo (Léopoldville); the diamond exports reached a record high in 1963 and were 16 percent of estimated total world production.

In 1962 the estimated gross national product (GNP) was CFAF 9,065 million (US$37 million); [2] the domestic mineral production has an estimated value of CFAF691 million, 7 percent of the GNP. The latter decreased to CFAF520 million in 1963, with a consequent drop in the share contributed by mining.

The outstanding event of the year was the announcement of the assignment of rights to develop the country's potash deposits to a company comprising several foreign investors and the Congo Government. The potash deposits represent the only important discovery of any current significance. The 1963 inauguration of large-scale production of manganese ore in adjacent Gabon brought minor economic benefits to the Congo because the ore is exported through Pointe Noire, the Congo's only port, after a 485-kilometer rail haul through Congolese territory. In 1963 manganese ore shipments from the port totaled 575,000 tons.

Data on employment in the extractive industries are not available. In 1956 about 2,000 workers were engaged in mining, and with the decreased production since then, the mine labor force has probably declined. At any rate, only a small part of the estimated 40,000 Congolese salaried workers in the estimated 1 million population are employed in mines, quarries, and oilfield activities.

GOVERNMENT POLICIES AND PROGRAMS

Other than the agreement of the Government with the new company to exploit the potash deposits, no specific new mining legislation has been reported. Law No. 39–62 of December 28, 1962,[3] which set up a new general tax structure, became effective upon publication. This code brought up to date earlier legislation, and stipulated depletion allowances for the extractive industries.

Following the revolution of August 1963, there was a change in the business climate, and expectations of lower retail sales, depletion of inventories, increased fluidity, and the movement of capital to France affected the mineral economy. A rather remarkable increase in construction activity, however, was expected for 1964 and would include six new Embassies, and a CFAF613 million sports complex to be completed in 1965 in the capital, Brazzaville. The liberal investment and reinvestment codes formulated in 1961 remained applicable and were applied to several investment conventions. U.S. investors remained eligible for protection under the Agency for International Development's Investment Guarantee Program applicable to the Congo.

During 1963 a Congolese 5-year plan, which came into operation on January 1, 1964, was prepared. Calling for a total expenditure of CFAF50 billion, of which 44 percent was for development of industry and services, the program included about CFAF90 billion for foreign capital investment. No significant progress was reported on the plans for the construction of the cement plant near Loutete or for the hydroelectric development on the Kouilou River, around which an industrial complex has been proposed. The proposed complex would include a plant to produce aluminum from imported alumina and other electrometallurgical facilities.

First steps towards creating a Congolese Bureau of Mines in the Ministry of Industrial Production were taken in April. The bureau was formed both to administer mining matters and to undertake exploration; it was considered that exploration by the bureau would be more advantageous than concluding exploration agreements with foreign interests.

SOURCE MATERIAL

Data on production and 1963 developments are from dispatches of the U.S. Embassy in Brazzaville amplified by the coverage of technical journals. Trade data are from the Union Douanière Équatoriale.

PRODUCTION

The 1963 production of all commodities was below that of 1962. Gold and lead, the major items in 1959, have declined since then, owing to the economically marginal nature of the gold deposits and exhaustion of the principal lead mine. The beginning of zinc and petroleum production in 1960 partly compensated for this decline, but output of

[3] Journal Officiel de la Republique du Congo (Brazzaville, Republic of Congo). Dec. 31, 1962, pp. 1019–1095.

Digitized by Google

the new commodities has shown annual variations, marked by the sharp drop for zinc since 1961 and the 1963 decline for petroleum. Production data for building materials are not available; the country's requirements, other than those of cement and lime, are met mainly by domestic production. Output of building materials probably grew during 1959–63, and 1963 may have been comparatively high. However, output apparently did not attain the level established when the extensive port developments at Pointe Noire (to permit the evacuation of the Gabon manganese ore) were underway.

[1] In addition, building materials are produced; but quantitative data are not available.
[2] Metal content of marketable ore or concentrate produced, except gold which is fine metal recovered in mining.
[3] Estimate.

TRADE

In 1962 the total value of metal and mineral imports was CFAF2,140 million, or 13 percent of all imports, compared with CFAF2,917 million and 15 percent in 1961. The 1962 distribution of import value by categories follows: Metals, CFAF830 million; nonmetals, CFAF347 million; and mineral fuels, CFAF963 million. Exports were valued at CFAF4,015 million (CFAF640 million in 1961) and comprised 47 percent of all exports (13 percent in 1961). The increase in 1962 was due to the greatly increased exports of diamonds, presumably originating in the Republic of the Congo (Léopoldville). In 1962 exports of these diamonds were valued at CFAF3,149 million (CFAF33 million in 1961), accounting for 78 percent of all mineral and metal exports and 37 percent of all exports. The 1962 exports of metals were valued at CFAF197 million, and exports of mineral fuels were valued at CFAF669 million.

France continued to be the country's leading supplier of metals and minerals, with 54 percent of the total; the European Economic Community, of which the Congo is an associate member, supplied 60 percent in the aggregate. The Netherlands Antilles and Venezuela, main suppliers of petroleum refinery products, ranked second and third, respectively, followed by the United States. The latter country supplied 4 percent of all mineral and metal imports; these commodities, mainly petroleum refinery products and rolled steel, comprised 14 percent of all the Congo's imports from that source. Belgium-Luxembourg was the chief recipient of mineral and metal exports, with 46 percent of the total, followed by France (13 percent) and the United States (12 percent). These exports, consisting solely of diamonds, comprised 92 percent of all exports to the latter country.

Digitized by Google

Preliminary data on 1963 metal and mineral trade place the total value at CFAF2,051 million for imports and CFAF5,113 million for exports; of the latter, diamonds amounted to CFAF4,759 million.

COMMODITY REVIEW

METALS

Copper.—The small copper output, 65 percent below 1962, continued to come from the M'Passa mine in the Niari Valley, where Syndicat de M'Passa (SMM) began production in 1961. Copper was produced as a byproduct of mining lead-zinc; the principal economic mineralization of the lenses was estimated to contain about 55,000 metric tons of ore. The Syndicate is an association of the Bureau de Recherches Géologiques et Minières (BRGM), an agency of the French Government, and Compagnie Minière de Congo (CMC), formerly operators of the Mindouli copper mine and the lead mines at M'Fouati and Hapilo, which were worked out or uneconomic at prevailing prices. The 1963 production was 830 metric tons of concentrates estimated to contain 35 percent copper.

Gold.—Gold continued to be produced only by individual African miners using primitive hand methods and declined 20 percent below the 1962 output. Exports in 1963 were 2,765 troy ounces.

Lead and Zinc.—The M'Passa mine of SMM also accounted for the country's lead and zinc output, producing 2,229 metric tons of bimetal concentrates containing, as in 1962, an estimated 15 percent lead and 32 percent zinc. These grades are lower than the average for the ore reserved, estimated to be 21 percent lead and 35 percent zinc. No progress was reported toward the development of the new discoveries made by the Syndicat de la Loutete, another association of BRGM and CMC; these discoveries consist of 15,500 metric tons of 14 percent lead ore at Yanga-Koubenza and 40,000 metric tons of 13 percent lead ore at Palabanda.

Tin.—The 1963 tin production came from two small veins of cassiterite found in the Mayumbe. Output was maintained at the approximate level of the preceding year; production was 58 long tons of concentrates containing an estimated 75 percent tin. Other scattered cassiterite deposits in the area remained unexploited because of the high costs of mining and transport to Pointe Noire.

NONMETALS

Diamond.—Although a small diamond production was recorded in the past, it never exceeded 1,000 carats annually and ceased prior to 1959. Exploration by Diamant-Congo in the Lali-Bouenza area revealed extensive flats which might be exploited mechanically; however, no effort to undertake their development was reported in 1963. Additional promising finds in northern Congo were reported in the year. Diamond was the largest single item of Congolese exports. Almost all of the diamond arrived in Brazzaville from Congo (Léopoldville) but did not appear in the import figures. To regularize their trade, the government has licensed about 12 buyers for these stones and facilitated their export by levying only a 2-percent ad valorem export tax. The 1963 exports were 5,684,000 carats; estimates were that 341,000 carats were gem quality and 5,343,000 carats were industrial stones. Average value per carat was CFAF891 (CFAF1,198 in 1961). Dia-

Digitized by Google

mond exports to the United States declined appreciably from those of 1962.

Potash.[4]—In April 1963, potash-mining rights were assigned to Société des Potasse de Hollé (SPH) by the Government of the Congo. Discovered in 1960, the deposits near Hollé, 45 kilometers inland from Pointe Noire, were explored by a French group consisting of Société des Pétroles d'Afrique Équatoriale, Bureau de Recherches Géologiques et Minierès, and Les Mines de Potasse d'Alsace. The initial exploration included 7,645 meters of drilling within an area of 4,000 square kilometers, and by mid-1963 expenditures amounted to CFAF907 million. SPH was formed to exploit the deposits by the companies involved in the exploration, the Congolese Government, and reportedly Israeli, German, and possibly U.S. potash producers. World Bank financial assistance may be given. An annual production of 2 million metric tons is envisaged; of this 600,000 tons will be treated locally and will yield 350,000 tons of potassium oxide (K_2O), practically all for export. The remainder will be exported in untreated form. The projected total investment is about CFAF12 billion, and production is scheduled to begin in 1967. Employment is expected to be 700 to 800 personnel of all categories in mining, treatment, and transportation.

The potash occurs within the coastal sedimentary basin, as part of a thick salt series averaging 500 to 600 meters in thickness; the top appears at depths of 250 to more than 600 meters. This series contains several potash horizons, consisting essentially of carnalite which occurs as numerous beds up to 15 meters thick. Sylvanite is also present as beds or lenses, less frequent but thicker than those of carnalite.

MINERAL FUELS

Petroleum.—Congolese petroleum production dropped to approximately the 1961 level, 11 percent below that of 1962. The output came entirely from the Pointe Indienne field near Pointe Noire, where Société des Pétroles d'Afrique (SPAFE), partly owned by the French Government, began production in 1960. At the beginning of the year nine wells, all flowing, were producing. Previously announced plans for increasing the Pointe Indienne annual production to 150,000 metric tons were delayed in their implementation, probably because of the limited reserves of the field, placed at less than 1 million tons at the beginning of the year. The gas deposits, also in the Pointe Indienne field and containing an estimated 142 million cubic meters, remained unexploited. SPAFE continued exploration within the Pointe Indienne concession; exploration activities were begun within the offshore Pointe Noire and Nord Kouilou permits, covering respective areas of 3,950 and 3,564 square kilometers. In the offshore exploration, SPAFE is associated with Mobil Oil, Mobil West Africa, and Shell Oil. No discoveries resulting from the 1963 activities were reported.

In December it was reported that an affiliate of the Italian Ente Nazionale Indrocarburi (ENI), after 2 years of negotiations, had

[4] Canadian Mining Journal (Gardenvale, Quebec). V. 85, No. 2, February 1964, p. 164. Industries et Travaux d'Outremer (Paris, France). V. 10, No. 106, September 1962, p. 729.

758-002—65——57

Digitized by Google

received final permission to enter the retail market trade and immediately began the construction of at least six service stations. These stations were expected to be supplied by the ENI-affiliated refinery at Tema, Ghana.

The Republic of Congo participated with its partners in the Equatorial Customs Union (Central African Republic, Chad, and Gabon) and nearby Cameroon in the successful negotiations for the establishment of the 700,000-metric-ton petroleum refinery at Port Gentil, Gabon, to be in operation by 1966.

Preliminary 1963 data place the 1963 exports of crude petroleum at 101,100 metric tons with an average per-ton value of CFAF 3,314 (CFAF 3,322 in 1962). Imports of petroleum products included gasoline 28,700 tons; kerosine 6,600 tons; fuel oil (all types) 39,600 tons; and lubricants 3,400 tons.

The Mineral Industry of the Republic of the Congo (Léopoldville)

By Thomas G. Murdock [1]

DURING the first half of 1963 the mining and metallurgical industry of Katanga, the country's principal productive area, was recovering from damages caused by the hostilities attending reunification. Despite the loss of production while damaged productive, power, and transportation facilities were being reestablished, the year's performance for the country as a whole compared favorably with that of the preceding year as the output of some commodities improved. The extractive industries still occupy a preponderant place in the Congo economy; they produce currently about two-thirds of the country's revenue in hard currency and employ the largest single portion of the Congolese labor force.

Since World War II the Congo has shown an almost constant growth in its diversified mineral production and has maintained its rank as the leading world producer of cobalt and industrial diamond; it is the sixth world copper producer and an important supplier of manganese, columbium-tantalum minerals, and germanium. Because of its previous association with Belgium and extensive Belgian private investment, that country has been the principal customer for Congo metals and minerals. Most Western European countries rely on the Congo as a major source of minerals and crude metals. The Congo has also been an important supplier of minerals to the United States, particularly those items of which U.S. domestic supply is deficient. In 1961 the Congo's gross national product (GNP) was CF61 billion (US$1,220 million [2]); the 1962 value of mineral production was CF16.1 billion, or 26 percent of the 1961 GNP, exclusive of clandestinely mined diamonds and gold. In 1963 the total taxes and imposts paid by Union Minière du Haut-Katanga, the country's principal mining company, amounted to CF1,665 million (CF1,485 million in 1962).

The bulk of Congo ores were converted to metallic form in domestic smelting and refining facilities prior to export, thus insuring the maximum return to the local economy.

In addition to making important contributions to the country's budget, the mining industry also has made major contributions to the

[1] Mining engineer, Division of International Activities.

[2] In this and other references to values US$1=CF50. Actually the official exchange rate of the Congolese franc, formerly on par with the Belgian internal franc at this exchange, declined to US$1=CF65 following independence and market rates reached about 600 percent of the official rate. After the Congo became a member of the International Monetary Fund in September 1963, the franc was given a more realistic value, CF180 per US$1 for importers and CF150 for exporters.

Digitized by Google

development of rail, road, and river transport systems and to the establishment of extensive power generating facilities. It has pioneered the social development of the country and created a trained and stable labor force, constructing cities, schools, and hospitals for its employees and the general population of the mining areas.

Although 1963 saw important events in the political field, including the start of the reintegration of Katanga, the economy of the country evidenced little progress. The major event in the economic field was the monetary reform or devaluation, undertaken to prevent a further deterioration in the country's precarious economy. This measure was expected to benefit the mining industry at least temporarily, by easing the pressure on profit margins caused by rising wages and prices and an unrealistic rate of exchange. However, a 25-percent wage increase was expected to limit the benefits of devaluation. The greatest need of the mining industry was reported [3] to be a speedy restoration of secure and stable conditions. A major problem has been presented by the many resignations of European supervisors and other employees, who prematurely terminated their careers in the country, and of African employees, who have returned to their places of origin. Difficulties in obtaining replacement parts for equipment and shortages of skilled maintenance employees have created a certain hardship for mining companies. According to newspaper reports,[4] one cause of the economic difficulties in Katanga has been the inability to obtain the 50 percent of the hard currency earned by this province; this was to be returned to Katanga for its needs by the Central Government, in accordance with the national reconciliation plan. Rail communication from industrial centers in the Katanga to Lobito (Angola) and Beira (Mozambique) was reestablished, and exports were resumed in February. Reestablishment of transportation over the rail-river route, permitting movement of Katanga exports to Matadi via Léopoldville, was completed at the end of August with the rebuilding of the bridge over the Lualaba.

Despite the abnormal operating conditions which have prevailed in the Congo since mid-1960 and some recession in markets, the major producing companies have shown profit balances. However, these have declined steadily from year to year, and the 1963 profit of the largest company was 44 percent below that of 1962. The inability of the Congo Government to provide foreign exchange has prevented payment for dividends for 1961 and subsequent years.

The most outstanding 1963 development in the expansion of productive facilities in the Congo was the laying of the cornerstone for the new Société Congo-Italienne de Raffinage (SOCIR) oil refinery at Kinlao in the Bas Congo on September 26. SOCIR is owned on a 50–50 basis by the Congo Government and the Italian State-owned Ente Nazionale Idrocarburi (ENI). Half of the estimated cost of $12.7 million is to be raised by the Congo Government, which will share equally with ENI in the profits. The new refinery is to have

Digitized by Google

a capacity of about 12,000 barrels of crude petroleum per day by 1965, at which time it should be able to supply all of the Congo's requirements for gasoline and fuel oils.

GOVERNMENT POLICIES AND PROGRAMS

Apart from the legislation covering licensing and exchange controls and endeavoring to curb illicit trade in diamonds and gold, no important laws directly pertinent to the mineral industry have been enacted since independence. In the absence of superseding legislation, the mining code prevailing under the Belgian Congo administration has been continued, and mineral resources constitute property distinct from that of the surface and belong to the State. The Central Government thus has been vested with the sole authority to fix the general conditions and terms under which prospecting and exploitation may be carried out. Mining rights have been granted by the Provincial governments since the dissolution of the "chartered" organizations formerly authorized to do this.

On December 6, 1963, the Congolese Minister of Lands, Mines and Energy issued a public letter warning concession holders that if they did not exploit their concessions, these would be forfeited under article 90 of the Mining Decree of September 24, 1937, which specified the maximum time permissible before exploitation must start and during which operations may be suspended. Expectations were that the determination of the government to enforce this article might lead to an increased activity.

An address by the Congolese Vice Prime Minister in June contained the first major statement of government policy toward economic development. This included several items of significance, particularly encouragement of existing investments, economic stimulation of the infrastructure inherited from the colonial economy, making a detailed inventory of natural resources actually being exploited and of others not yet in production, improving the technical educational level of the people, and organizing a national council to study the problems of conservation and utilization of renewable and nonrenewable natural resources.

SOURCE MATERIAL

Background information is from extensive files of U.S. Foreign Service dispatches, mining company annual reports, and other publications. Accounts of current development are meager and come chiefly from annual reports of the Union Minière du Haut-Katanga. The latter source has also provided the most reliable production data. For some products it has been necessary to resort to other sources and estimates have been used for some years because the normal transmission of these data by the U.S. Embassy in Léopoldville was interrupted by the lack of reliable statistics. The separation of parts of the country from the Central Government also made it impossible to obtain recent complete data on mineral trade; consequently, reliable detailed statistics for the country as a whole cannot be presented for years subsequent to 1959. Partial figures are available for 1960; for

Digitized by Google

later years an effort can only be made to show the general magnitude of the trade through resorting to several indicators of varied reliability.

PRODUCTION

Production trends reflect both world market conditions and local events in the Congo during recent years. The effect of additional productive capacity of the Katanga base-metal complex was evident in the increased output of some metals; if unfavorable operating conditions had not intervened following the completion of the new facilities, output could have been greater. Considering the magnitude of the disturbances throughout the country, the loss of production was the minimum possible. Individual commodities have shown different production trends; the declines in output were due, at least in part, to the prevailing chaotic conditions, with the possible exception of manganese, which comes from an area relatively free of political disturbances. Several producing facilities were centers of hostilities; particularly the Luena coalfields, the Manono tin mines and smelter, and more recently the various installations in the Katanga copper belt. Uranium production ceased in 1960 owing to exhaustion of ore. Copper output has been smaller than productive capacity, partly because of reductions in program in an effort to coordinate production with market demand and thus to stabilize price; cobalt demand has also declined in some years.

[1] U.S. imports.
[2] Final figure; supersedes figure given in commodity chapter of volume 1.
[3] In addition, tin-columbium-tantalum concentrate was produced as follows: 1959, 1,258,000 kilograms; 1960, estimated 680,396 kilograms; 1961–62, not available; 1963, 26,000 kilograms.
[4] Including recoverable copper in exports of cathodes, blister copper, cobalt-copper alloy, zinc concentrates, and other products.
[5] Including WO_3 in tin-tungsten concentrates.
[6] Estimate.

Digitized by Google

Although in 1962 the output of several commodities was below that of immediately preceding years, the total value (CF16.1 billion) reflects a growth of 18 percent over that in 1952 (CF13.7 billion).

TRADE

The value of mineral exports consistently has been several times that of the imports, and through 1959 showed an almost constant increase, despite sometimes fluctuating market values of the principal commodities. In 1959 mineral exports were valued at CF13,976 million, 56 percent of that of all exports. Exact value of 1960 mineral exports is not available; on the basis of available data it is estimated at CF13,000 million, 6 percent below that of 1959 and at about the 1953 level. Data are insufficient to estimate values of mineral exports in subsequent years. Indicative of these, however, are the value of aggregate 1961 imports of major mineral commodities from the Congo by Organization for Economic Cooperation and Development (OECD) countries, CF12,000 million, and of 1962 mineral exports from Katanga, CF9,445 million. Belgium has continued to be the principal recipient of Congo minerals; of the 1961 imports by OECD countries, 74 percent were by that country. The United States has been a steady customer for several Congo products, particularly cobalt, manganese ore, and zinc metal; total value of U.S. imports in 1962 was approximately CF660 million.

In August 1964 partial data on 1963 exports of metals became available. Exports identified as quantities shipped to final destinations from the ports of Lobito (Angola), Beira (Mozambique) and Mombasa (Kenya) were as follows: cadmium, 370,000 kilograms (all to Belgium), cobalt-copper alloy and electrolytic cobalt, 813 and 7,047 metric tons, respectively (all to Belgium); copper, 236,599 metric tons, (Belgium, 161,715 tons, France 27,445 tons, and Italy 21,124 tons), germanium concentrates, 9,000 kilograms (all to Belgium); zinc concentrates, 131,903 metric tons (Belgium, 123,772 tons and France, 8,131 tons); zinc in ingot form, 30,157 metric tons (United States, 9,017 tons; West Germany, 5,564 tons; United Kingdom, 4,295 tons; and Italy, 3,400 tons); and anode slimes, 8,000 kilograms (all to Belgium). The above exports from depots in neighboring countries had a total estimated value of CF10,980 million at an average exchange of CF69.43 per US$1. Shipments of metals to the depots were valued at CF11,345 million, 47 percent of the value of all exports.

Despite the extensive development of the Congo minerals industry, the country remained dependent upon imports of fuels, iron and steel, some nonferrous metals, and many nonmetallic minerals. In 1959 the total value of imports of these was CF2,560 million, compared with CF649 million 10 years earlier. The 1959 import value by categories follows:

	Francs, million	*Percent*
Metals	901	35
Nonmetals (except fuels)	194	8
Mineral fuels	1,465	57
Total	2,560	100

TABLE 2.—Exports of major metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1959	1960	Principal destinations, 1960 [2]
Metals:			
Beryl	454	419	United States 384; Japan 23.
Cadmium kilograms	585,655	[3] 508,000	Belgium 113,798; France 106,000; United States 2,721.
Cobalt and alloys	11,871	7,362	Belgium 6,286; United States 1,074.
Columbium-tantalum minerals kilograms	370,000	203,000	United States 150,786.
Columbium-tantalum slag do	153,302	819,000	Netherlands 510,000; United States 309,000.
Copper [5]	283,580	284,494	Belgium 208,523; Italy 33,655; France 32,927.
Germanium dusts	178	[4] 187	All to Belgium.
Gold troy ounces	385,327	355,748	Do.
Manganese ore [5]	302,397	304,815	United States 128,113; Belgium 71,661; West Germany 35,036.
Tin:			
Concentrate long tons	10,158	9,000	Belgium 8,508; United Kingdom 355; Tanganyika 111.
Metal [5] do	2,820	2,529	Belgium 3,298; United States 336; West Germany 184.
Tungsten concentrate	1,016	1,177	Belgium 634; United States 182; Netherlands 120.
Zinc:			
Concentrate [5]	75,131	97,540	Belgium 90,263.
Metal	54,439	50,803	United Kingdom 14,335; United States 8,443; Republic of South Africa 609; West Germany 305.
Nonmetals (except fuels):			
Cement	43	[4] 406	Republic of Congo (Brazzaville) 400.
Diamond thousand carats	15,954	10,356	United Kingdom 10,288; Belgium 68.
Lithium minerals	2,990	1,500	All to West Germany.

[1] Includes the trusteeship territories of Ruanda-Urundi through June 30, 1960.
[2] Exact data unavailable in most cases. Figures shown are estimated based on 1959 or partial 1960 deliveries, or receipts by known destinations.
[3] Estimate, from Overseas Geological Surveys, Statistical Summary of the Mineral Industry.
[4] January-June only.
[5] Receipts by countries in 1960 indicated by OECD trade statistics. Excess over exports are due to difference in quantities in transit at beginning and end of period.

Source: Bulletin de la Fédération des Associations Provincales des Entreprises du Congo, May 1962.

The 1959 mineral imports accounted for 17 percent of all imports on the basis of value. Belgium was the principal supplier with 30 percent of the total; the United States supplied 7 percent. Data on the value of mineral imports in subsequent years are so incomplete that they mean little. In 1960, exclusive of Katanga and South Kasai Provinces in the second semester, the total value was CF1,471 million. The 1962 value of mineral imports of Katanga Province, exclusive of fuels, has been reported at CF419 million. Since 1960, mineral imports have declined drastically owing to the precarious economic position of the country and particularly the need to allocate scarce foreign exchange to foodstuffs and other vital imports. The decrease in mineral imports was reflected in the decreased value of all imports, from CF15 billion in 1959 to CF8 billion, exclusive of Katanga, in 1962. The foreign exchange made available to importers in 1963 was reportedly equivalent to CF10 billion.

COMMODITY REVIEW

Unavailability of recent complete data on imports makes it difficult to estimate consumption. Undoubtedly the necessity of limiting imports during recent years has meant that consumption has been well below the 1959–60 imports and stocks have declined greatly. The suspension of most construction activities throughout the country meant that consumption of iron and steel products and building materials dropped to insignificant proportions. Cement consumption for the entire country dropped from 425,000 tons in 1959 to 135,000 tons in 1961 (133,107 tons exclusive of Katanga in 1962). U.N. statistics indicate 1961 energy consumption at 1.25 million tons of standard coal equivalent of which 0.39 million was of domestic origin, compared with 1.40 and 0.60 million in 1958. Except for small quantities of copper, tin, and zinc consumed locally, all metal production is for export, and thus 1959–60 imports of these probably closely approximate consumption.

METALS

Aluminum.[5]—Interest has been revived in the possibilities of hydroelectric power development at Inga on the Congo River upstream of Matadi and the establishment of aluminum production facilities there. In 1963 Italian consultants were asked to prepare a development plan, and the Congo Extraordinary Budget for 1964 contained an appropriation for preliminary work on the project.

Beryl.—The production of beryl, which began in 1954 and reached a high of 1,686 metric tons in 1956, has declined appreciably since.

[5] Mining Journal (London). Aluminum-Re-examination of the Inga Scheme. V. 262, No. 6699, Jan. 10, 1964, p. 23.

Digitized by Google

Beryl was extracted with cassiterite with which it is associated in certain pegmatite dikes. Thus the quantity recovered depends upon cassiterite output. The production has been entirely by Compagnie Minière des Grands Lacs from the Lusungu, Mapembe, and Kobokobo deposits in Kivu Province. The mineral is obtained by handsorting from the pegmatite; beryllium oxide content is 10 to 13 percent.

Cadmium.—Cadmium was recovered from the copper and zinc concentrates obtained from sulfide ores from the Prince Leopold (Kipushi) mine of the Union Minière du Haut-Katanga. Part of the cadmium content is volatilized when the copper concentrate is smelted at Lubumbashi and when the zinc concentrate is roasted at Jadotville. This part is recovered from flue dusts. The portion that is not volatilized during the roasting of the zinc concentrate is recovered as cadmium cement when the roasted concentrate is treated in the electrolytic zinc plant of Société Métallurgique du Katanga (METALKAT) at Kolwezi. The treatment of the cadmium-bearing flue dusts by METALKAT also yields cadmium cement. All the cements are delivered in solution, and this is treated by electrolysis. The cadmium cathodes thus obtained undergo a double refining in an electric furnace before being cast into rods for marketing.

Cobalt.—The Congo possesses extensive cobalt reserves and its single cobalt-producing company, the Union Miniére du Haut-Katanga, has accounted for over 63 percent of free world cobalt output during the past decade. The production is mainly as a coproduct of the hydrometallurgical treatment of copper concentrate from company mines near Kolwezi and Jadotville. Formerly the ores and concentrates especially rich in cobalt were reduced in the Panda electric furnace plant at Jadotville, to yield a copper-cobalt-iron alloy with 46 percent cobalt. They were exported to Belgium for refining into commercial forms. The Panda plant was closed down in September 1962, with the completion of facilities for the production of electrolytic cobalt at the Luilu plant near Kolwezi; subsequent production has been as electrolytic cobalt, most of which was refined into granules.

Cobalt is recovered from copper ores containing only a little of the element by leaching it at the same time as the copper, in the Shituru plant at Jadotville and the Luilu plant. The spent solution, after electrolysis for copper, is purified, and the cobalt is precipitated as a hydrate. This is put back into solution and recovered by electrolysis. The new Luilu plant has a rated capacity of 3,500 metric tons per year under normal conditions; the cathode cobalt produced there is refined in the electric furnace plant at Shituru. The hostilities in December 1962 demolished part of the Shituru cobalt plant. It became operative again only some months later, thus accounting for the decline in production in 1963 to a level only slightly above that of 1958. The 1963 output consisted of 4,827 metric tons of electrolytic cobalt in granules, 1,996 tons of recoverable cobalt in exported cathodes, and 553 tons of recoverable cobalt in exported cobalt-copper alloy.

Columbium-Tantalum.—The Congo has been an important producer of columbium and tantalum minerals and with the former trusteeship area of Ruanda-Urundi supplied 10 percent of free world production in 1953–57. As reflected in imports to the United States,

Digitized by Google

the principal customer, activity has declined drastically during recent years; actual output data are not available. This decrease has been mainly due to the troubled conditions which have existed in the producing areas, particularly at Manono, where Compagnie Géologique et Minière des Ingénieurs et Industriels Belges (GEOMINES) has been the largest producer. At Manono, as in several parts of Kivu Province, columbite-tantalite is produced; usually deposits are worked for cassiterite. The two minerals are normally intimately associated, and part of the production is of a mixture of the two with cassiterite. Congo columbite-tantalite assays 70 to 75 percent combined pentoxides. Separation of columbite-tantalite from cassiterite is by magnetic sorting in the last stage of the concentration. The tin ore smelted at Manono contains comparatively high percentages of columbium-tantalum minerals, and these go into the slag which is exported; production of this slag was curtailed by the inactivity at Manono during the height of the disturbances there. Activity in Kivu has likewise been on a reduced scale; exploration of the Luesche pyrochlore deposit continued during 1963, but production was not started. Compagnie Minière des Grands Lacs has been the principal producer of columbite-tantalite in Kivu.

Copper.—In 1963 the Union Minière du Haut-Katanga production of copper ore, together with accompanying quantities of cobalt ore from the western mines and of zinc ore from Kipushi, totaled 5,443,874 metric tons (9,147,869 tons in 1962). Except for Kipushi and a section of Kambove West, which are exploited by underground mining, all mines are worked by opencuts. Output of individual mines follows:

Sector and mine:	*Class of ore*	*Production (metric tons)*
Western:		
Kamoto	Siliceous oxides	1,369,039
Ruwe	Oxides in breccia	1,103,090
Musonoi	Mixed oxides-sulfides	1,339,666
Kolwezi	Oxides	276,608
Central:		
Kambove West	Mixed oxides-sulfides	252,858
Kakanda	Oxides	191,565
Southern:		
Prince Leopold (Kipushi)	Copper-zinc sulfides	896,679
Ruashi	Oxides	14,024
Other		345

Digitized by Google

Total feed to beneficiation plants, including ore withdrawn from stockpiles, was 7,363,365 metric tons; production data for individual plants follow:

Concentrator	Metric tons treated	Concentrates produced			
		Metric tons	Grades (percent)		
			Cu	Co	Zn
Kolwezi	3,839,160	600,533	25.33	1.70	
Kipushi	904,109	158,653	27.66		
		175,263			59.08
Kambove	793,115	107,738	31.29	1.63	
Kambove (washer)	109,666	[1] 53,074	7.18		
Kakanda	507,485	52,975	24.51	.85	
Ruwe (washer)	[2] 1,147,386	56,336	22.24		
		[1] 40,795	5.62		
Ruashi (washer)	62,444	9,848	18.87		
		6,620	7.30		

[1] Products retreated in concentrator.
[2] Includes 18,946 tons of intermediate products retreated.

Pyrometallurgical operations were carried out in the Lubumbashi smelter at Élisabethville, where matte production in water jacket furnaces was 110,318 metric tons; the converter plant produced 69,866 tons of blister for export. The Shituru electrolytic plant produced 107,424 metric tons of cathodes and 9,486 tons of starting sheets. The adjacent refinery, treating part of the cathodes and products from other plants, produced 131,484 metric tons of electrolytic quality and 24,895 tons of anodes for starting sheets. The Luilu electrolytic plant produced 91,282 tons of cathodes and 9,143 tons of starting sheets. The 1963 balance of copper in exportable products follows:

	Metric tons
Electrolytic copper in ingots	130,602
Recoverable copper in cathodes exported	67,726
Recoverable copper in blister exported	71,310
Recoverable copper in cobalt-copper alloy exported	178
Recoverable copper in zinc concentrates and other products	108
Total	269,924

The decreased 1963 production was mainly due to the shutdown early in the year when facilities were being reactivated, following the end of hostilities on January 14, when the Katanga Government terminated the secession and confirmed its adhesion to the Thant plan. The company announced [6] that in 1964 copper production will not be significantly greater than in 1963.

Germanium.—This metal is present in very small amounts in the copper-zinc ores of the Union Minière Prince Leopold mine as the sulfide mineral renierite. It accompanies the copper at the time of concentration at the mine. A first concentrate of germanium is obtained by passing the copper concentrate over magnetic separators. The rest is recovered from the cadmium-bearing dusts in the baghouse at the Lubumbashi smelter. These dusts are treated in the METALKAT

[6] Metal Bulletin (London). No. 4864, Jan. 17, 1964. p. 61.

Digitized by Google

plant at Kolwezi, where a germanium precipitate with 7 percent oxide is obtained and exported to Belgium, where the Hoboken plant of an associated company produces the oxide and metal in the extremely pure form required by the electronic industry. The interrupted operations at the Prince Leopold mine and the metallurgical plants account for the fact that production during recent years has been below the 1960 peak. The magnetic separators at the Kipushi concentrator were frequently shut down because of the low content of magnetic renierite in the copper concentrate.

Gold.—The gold deposits of the Congo are chiefly the eastern area stretching from the Congo River to the Sudan frontier and into Rwanda. In the small detrital deposits, the extraction is manual, while in the more important ones it is by mechanical shovel, dragline, dredge, and/or hydraulicking. The ore is concentrated by gravity in sluices or washers. Primary deposits yield about two-thirds of the normal production. The principal producers have been Société des Mines de Kilo-Moto, Compagnie Minière des Grands Lacs, Société Minière de la Tele, and Mines d'Or et d'Etain de Kindu (KINORETAIN). These producers accounted for 94 percent of the total production prior to the country's independence.

Gold production has diminished from year to year, due to political difficulties, the uncontrolled gold traffic, and the constant increase in working costs which has compelled many operators to curtail their activities or close their mines. The gold mines are mainly in Orientale and Kivu Provinces; these areas were involved in the 1961 struggle for power and by the end of 1963 had not wholly recovered from the damage.

Manganese.—Except for a few thousand metric tons annually from the Kasakalesa mine of Société de Recherche Minière du Sud-Katanga, a Union Minière affiliate idle in 1963, the Congo manganese production comes from the Kisenge mine of Société Minière de Kisenge. This operation, worked since 1950, is about 100 kilometers from Dilolo on the Angolan frontier and escaped the disorders which ravaged the rest of Katanga. However, the decreased 1963 output was partly due to inactivity early in the year when the power supply coming from Kolwezi was interrupted by military operations. The oxide ore mined at Kisenge, after crushing and washing or treatment in the sink-float plant, is exported via Lobito in Angola. Grade of marketable ore as reflected in U.S. imports of recent years has ranged from 48.1 to 50.0 percent manganese. Small quantities of manganese dioxide assaying 80 to 83 percent manganese oxide are mined.

The generally decreased production since 1960 has been the result of market conditions, particularly increasing competition. U.S. imports for consumption dropped 40 percent between 1961 and 1962 but improved substantially in 1963. Preliminary data indicate that shipments from the mine totaled 267,000 metric tons in 1963.

Silver.—Except for minor quantities of silver recovered during gold refining, all the silver of the Congo is recovered as a byproduct of the copper industry. Silver is present in the copper-zinc sulfide ores of the Prince Leopold mine; it accompanies the copper through its

Digitized by Google

various processes and is exported in the blister copper produced at Lubumbashi for subsequent recovery and refinement in Belgium.

Tin.—Although most of the Congo tin deposits are detrital, important primary deposits as pegmatites and quartz veins are exploited, usually by opencut mining. The production comes mainly from the Maniema region in Kivu and from Manono in northern Katanga. Mining methods include primitive panning, hydraulic mining, and mechanical mining by draglines and shovels. The major producers have been Syndicat Minière d'Etain and GEOMINES, and before independence they accounted for slightly less than one-half of the production. Other important producers in 1963 were Compagnie Minière des Grands Lacs, Compagnie Belge d'Entreprises Minières, KINORETAIN, and Société Minière de la Belgika. The tin-mining areas have been centers of political unrest, and conditions for the operators became extremely difficult, particularly in 1961. Improved conditions in 1962–63 permitted a partial return to normal operations, with the foreign exchange shortage proving a major handicap. The only smelter operation in the Congo is that of GEOMINES at Manono; production of tin metal continued there during 1963 and showed a remarkable increase over that of previous years, during which operations were completely stopped for over 7 months at one time and for shorter periods on other occasions.

Tungsten.—Tungsten from the Congo comes entirely from Kivu Province where it is normally associated with certain cassiterite deposits. Most of the tin companies also produced tungsten and export either a tungsten concentrate obtained by treating cassiterite concentrates by magnetic separation or a mixture of the two for separation in Belgium.

Zinc.—The Congo's zinc production comes entirely from the Prince Leopold mine of the Union Minière as zinc sulfide ore associated with copper sulfides. A subsidiary company, Société Générale Industrielle et Chimique du Katanga, treated 118,050 metric tons of Union Minière's zinc concentrate in its plant at Jadotville, obtaining 89,572 tons of roasted concentrate and 93,855 tons of sulfuric acid. Sales of 89,155 metric tons of roasted concentrate were made to METALKAT, which produced the Congo's entire output of electrolytic zinc at its Kolwezi plant. Crude and calcined concentrates delivered for export totaled 65,445 metric tons. The loss of production in early 1963, while normal activities at the mines and plants were being resumed, prevented zinc production from coming up to full capacity.

NONMETALS

Diamond.—Normal operations in the Tshikapa fields of Kasai Province, which formerly provided up to about 30 percent of the country's output of gem diamond, have not been possible since 1960. Tribal warfare, the absence of law and order, illicit diggings, and theft reportedly compelled the operators, Société Internationale Forestière et Minière du Congo and its affiliates, to suspend operations in February 1962; operations had not been resumed by the end of 1963.[7] A buying

[7] Mining Journal (London). Annual Review for 1963 (p. 183) May 1963, and for 1964 (p. 187), June 1964.

Digitized by Google

agency was maintained in the area to purchase diamonds from native miners, but was reported to be unsuccessful.

The problem of unauthorized exports continued to be serious. Unlicensed buyers operated on the frontiers, dispatching diamonds illegally to many destinations. Despite the heavy loss to the national revenue, the government had difficulties in effectively controlling illicit operations. The value of unreported diamond production in 1962 was estimated at between CF850 million and CF1,400 million.

The Lubilash diamond, 98 percent of which is industrial quality, is mined at Bakwanga in south Kasai by Société Minière de Bakwanga (MIBA). As contrasted with the Tshikapa area where weakly mineralized and scattered deposits have limited mechanization, at Bakwanga the concentration of the deposits and the large volumes to be treated have allowed complete mechanization of the operations. With an absence of disturbed conditions, MIBA had a reasonably satisfactory year in 1963 but was handicapped by difficulties in obtaining spare parts needed for the extensive equipment in service. Work continued on the construction of a new central sorting station and a new dam on the Lubilash; the cost of these and other improvements and new construction was CF280 million.

MINERAL FUELS

Coal.—Coal production by Charbonnages de la Luena, around Luena in north Katanga, has been greatly curtailed owing to heavy damage incurred in the various military operations. Of a high ash content and containing 34 percent volatile matter, the noncoking coal from Luena has never filled more than part of the country's needs. Mining difficulties in the Luena basin and exhaustion of the nearby Kisulu deposits necessitated the exploitation of the Kaluku where mining conditions are very unfavorable. This and the decreased output at the beginning of 1963, because of the destruction of railroad bridges over which the coal moves, combined to prevent production at a higher level.

The Mineral Industry of Ethiopia

By Thomas G. Murdock[1]

DESPITE a record of mineral activity that dates back to Biblical times, the occurrence of a wide variety of minerals, and continuing efforts to discover major ore deposits, the Empire of Ethiopia has remained of minor importance in the world mineral economy. In 1963, as in previous years, the productive activity consisted essentially of small-scale exploitation of gold and platinum deposits, recovery of marine salt at the principal Red Sea ports, and operation of a single small cement plant. However, the year was characterized by progress toward an expansion of the mineral economy through installation of mineral-processing facilities, development of the extensive potash deposits, and mechanization of the largest gold mines. Of significance also was the enactment of a new investment law, the granting of two petroleum concessions to U.S. companies, and further exploration.

The 1962 mineral production, exclusive of building materials other than cement and lime, had an estimated value of Eth$13.4 million (US$5.4 million);[2] of this, cement comprised Eth$8.2 million. The 1962 gross national product (GNP) was Eth$2,170 million; thus, the mineral industry contributed only 0.6 percent of the GNP.

Data on employment by the extractive industries are not available; however, including those engaged in quarrying, the total labor force presumably amounted to several thousand. These workers comprised only a small part of the 19.6-million population (1963 estimate), over 90 percent of whom were dependent upon farming or livestock raising.

GOVERNMENT POLICIES AND PROGRAMS

No new legislation specifically directed at mining was reported during the year; however, decree No. 51 of September 16, constituting a new investment law, effectively encourages private Ethiopian and foreign investment. Definitely stipulated as being applicable to mining and industrial enterprises, the law grants income tax exemption for 5 years to new enterprises investing not less than Eth$200,000 and to existing ones for 3 years upon expanding their activity through the investment of at least Eth$400,000. The law further grants exemptions from import and export duties and other taxes under certain conditions. It insures the provision of foreign exchange for remittance of profits, repatriation of net proceeds, and payment of interest and

[1] Mining engineer, Division of International Activities.
[2] The Ethiopian monetary unit is the Ethiopian dollar (Eth$). Exchange used in this section is Eth$1=US$0.4032 (US$1=Eth$2.40).

Digitized by Google

principal on approved foreign loan contracted by enterprises covered by the decree.

The year marked the beginning of the second 5-year plan, a program with emphasis on industrial development, following the completion of an earlier plan designed to provide for the development of transport and communications, which by and large fulfilled its principal objectives. Under the new plan, the extractive industries are scheduled to be allocated Eth$74 million in new investments and production is expected to grow at the annual rate of 53 percent. The establishment of several new mineral-processing enterprises during the year and progress towards setting up others indicate satisfactory progress on the plan; the new investment law is expected to encourage additional development.

Geological investigations completed in 1963 included the fieldwork involved in the survey of the resources of the Blue Nile Basin undertaken by the U.S. Bureau of Reclamation, in cooperation with other U.S. Government agencies and counterparts of the Imperial Ethiopian Government. The Ethiopian Ministry of Mines was scheduled to undertake investigations of asbestos deposits east of Harar and exploratory drilling of the Agametta iron deposits, 30 kilometers southwest of Massawa, where the new plan calls for a small production to start in 1964. The search for petroleum and further investigation of potash resources were continued by the foreign companies active in the country.

Following the successful completion of a 30-month program of training 30 young men from various parts of the country as prospectors and sending some of them abroad for further studies, plans to train a second group were announced.

Eritrea has been a fully integrated province of Ethiopia since late 1962, and it was expected that this will lead to the clarification of some Eritrean mining titles and to an eventual expansion of the mineral industry there.

SOURCE MATERIAL

Background data on the resources were published in 1949 [3] and have been updated by a paper [4] which became available in 1963. Additional information was contained in a recent official U.S. Government publication.[5] The dispatches of the U.S. Embassy at Addis Ababa supplied accounts of the principal events of 1963 and some information on production. Data on trade, production, and other subjects are from publications of the Imperial Ethiopian Government. Production quantities are not available for some minerals and those given by various sources often disagree, therefore, accepted figures may be erroneous in some cases. Value of production is a rough estimate, given only to show order of magnitude.

PRODUCTION

Although official data on 1963 production are available for only two items, estimates based on authoritative forecasts indicate a definite decline in production. Output of gold, the principal commodity, has declined steadily since 1959; the other minerals have shown variable trends. Unfortunately data on the quarry production are not available; building materials are plentiful around the principal cities, and with the public works program carried out in 1959–63, large quantities of dimension and crushed stone were used. Prospects are good for an increased mineral production in the near future.

TABLE 1.—Production of metals and minerals [1]

TRADE

In 1962 the total value of metal and mineral imports was Eth$25.3 million, 10 percent of all imports, compared with Eth$25.4 million and 12 percent in 1961.[6] The 1962 import value was metals Eth$9.5 million; nonmetals Eth$1.1 million; and mineral fuels Eth$14.7 million. Recorded exports of minerals and metals were insignificant; in 1962 they were valued at only Eth$1.2 million, mainly salt, while in 1961 they totaled Eth$4.2 million and also included gold, manganese ore, and scrap metals. In 1962 they were only 0.6 percent of all exports, which was 2.3 percent less than in 1961. Reexports of metals and minerals were only Eth$47,954 in 1962 (Eth$33,600 in 1961).

[6] The official Ethiopian year ending September 10, 1961, the only base for which 1961 data are available.

Digitized by Google

Petroleum products constituted 58 percent of the 1962 metal and mineral imports, and Iran and Saudi Arabia were Ethiopia's principal suppliers with 26 percent and 16 percent, respectively. Japan, principal supplier of iron and steel, ranked third with 10 percent. The United States provided imports totaling Eth$1.8 million, and the European Common Market, Eth$5.9 million. Imports of metals and minerals from the United States were only 4 percent of all imports from that country. Japan was the principal customer for 1962 Ethiopian mineral exports, receiving 71 percent.

Based on trade in the most important items, through the first semester of 1963 the imports dropped to an annual rate of Eth$18.3 million; comparable data for exports are not available.

TABLE 2.—Exports [1] of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961 [2]	1962	Principal destinations, 1962
Metals:			
Scrap:			
Ferrous	1,055	[3]	
Other	464	[3]	
Gold, troy ounces	31,898	[4]	
Manganese ore	11,000	[5]	
Nonmetals:			
Clay	[3]	6	Saudi Arabia 4; Sudan 2.
Fertilizers	[3]	20	All to Italy.
Marble	[3]	20	All to Sudan.
Salt	44,025	121,923	Japan 94,266; France 10,441; Kenya 9,751; Malaya 5,000.

[1] Reexports are reported as follows: 1961, coal 440 tons and steel wire valued at Eth$500; 1962, steel pipe valued at Eth$35,962 (Italy Eth$32,400, Yemen Eth$3,542) and petroleum products valued at Eth$12,002 (Kenya Eth$5,448, French Somaliland Eth$3,531, Aden Eth$3,023).

[2] Year ending Sept. 10, 1961.

[3] Statistics available do not show exports of these items.

[4] Gold exports have been indicated only for alternate years since 1957.

[5] None shown for 1962. U.S. receipts were (calendar years) 1961, 6,015 tons and 1962, 6,292 tons.

COMMODITY REVIEW

METALS

Aluminum.—In May the local press reported that an aluminum-fabricating plant will be constructed and managed by the Chandarian Group (an Indian group with other industrial and commercial interests in East Africa), which will supply the initial capital of about Eth$278,000. The plant is to produce household utensils and light houseware from imported semimanufactures.

Gold.—The alluvial gold deposits at Adola in Sidamo Province, exploited by the Ethiopian Government, continued to supply most of the country's production. In 1962 these deposits, together with the small ground sluicing operations on the Kape River near Alghe, accounted for 25,721 ounces of the total. The remaining 2,315 ounces came from the two vein gold mines in Eritrea, which treat about 25 tons of ore per day each; these are the Ugaro mine of Eritrean Mining Co. and the Medrizien mine near Asmara. The production decline of recent years at Adola is reportedly due to the cessation of hand mining in certain areas while they are being prepared for mechanical mining. The government has an intensive program of mechanization underway at Adola for which Yugoslav credit of Eth$3 million was obtained. In April an order was placed with the Yugo-Inex Co. for equipment valued at Eth$793,600. This program is scheduled for completion in 1964.

Iron and Steel.—On February 13, the Emperor inaugurated the small plant of Ethiopian Iron and Steel Co., to remelt ferrous scrap in a 2,500-kilowatt electric arc furnace for casting ingots. The ingots are then reheated in an oil-fired universal heating furnace and rolled into round bars 6 to 24 millimeters in diameter. Situated at Akaki, 19 kilometers from Addis Ababa, the plant employed 170 people and daily production was 25 tons of bars. With no recorded exports of ferrous scrap in 1962, supplies were apparently stocked pending the completion of this facility.

Manganese.—The small production of manganese ore continued to come from the mine of Tigre Mining Concession at Enkafala, about 20 kilometers southwest of Dallol. The ore is trucked 140 kilometers from the mine to the port of Mersa Fatma and taken from there in small boats to Massawa for transshipment to market. Reserves of the area are believed not to exceed 75,000 metric tons; however, the high manganese content (51.3 percent for U.S. imports) have facilitated exploitation despite the remoteness from tidewater.

Platinum.—The operations of the Ethiopian Government at Yubdo in Wollega Province continued to produce placer platinum by hand washing. Production was at the approximate level of recent years. The mine has been in operation for over 30 years and major reserves are mined out. An extensive exploration with Banka drills was effected, and this outlined millions of cubic meters of low-grade platinum-bearing ground in the valley of the Birbir River below Yubdo. In 1963 the Ministry of Mines announced plans to mine this platinum at the rate of 6,000 to 8,000 ounces annually, using hydroelectric power to be produced on the Birbir, about 30 kilometers downstream from Yubdo. Geological investigations also revealed new bodies of plati-

Digitized by Google

num-bearing ultrabasic rocks extending northward from Yubdo to near Nejo.

NONMETALS

Cement.—In 1963 cement production continued to be supplied by the Dire Dawa plant of the Ethiopian Cement Corp., which operated at approximately full capacity. During the year construction was underway on a new 70,000-metric-ton-capacity plant at Nefas Selk on the outskirts of Addis Ababa. Limestone will come from the canyon of the Mugher River about 78 kilometers northwest of the plant, and a 10-kilometer aerial tramway will raise the rock 880 meters vertically from the quarry to the truck terminal. Clay will be obtained from an area near the plant and gypsum from Douanle, near the border of French Somaliland. Production is scheduled to begin in 1964.

In April agreement was reached with Friedrich Krupp of Rheinhauser, West Germany, for the construction of another 70,000-metric-ton-per-year plant at Massawa. Construction was scheduled to begin later in the year.

Potash.[7]—In 1963 the Ralph M. Parsons Co. of Los Angeles continued work in preparation for the development of the potash deposits near Dallol, in the northern part of the Danakil Depression inland from the Red Sea. Since 1958, exploration of the deposits has been in progress within the 90,000-square-kilometer concession, resulting in the discovery of at least 50 million metric tons of sylvite and other potassium-bearing minerals in a sedimentary zone about 3 meters thick and with an average dip of only 2°. The deposits are of Quarternary Age and are associated with substantial reserves of gypsum and rock salt. During the year drilling was continued to increase reserves, particularly to test formations for planning mining methods and development.

The Dallol deposits were worked on a small scale from 1915 to 1929 by an Italian concern. The new attempt to work them calls for an expenditure of Eth$37 million, in addition to the Eth$5 million invested since 1958. It involves the construction of a treatment plant at Dallol, including rodmills, flotation cells, large centrifuges, and a diesel-electric powerplant; a 100-kilometer standard gage railway from the plant to the Red Sea; a new deepwater port at Ras Andarge, just west of Thio on the Red Sea; and, a shallow inclined shaft to be driven to the beds from a point near the western edge of the Danakill Depression. Construction was planned to begin in the latter part of 1963, and production was scheduled to begin in 1965 with an initial annual output of 300,000 metric tons of exportable material expected to have a potash content equivalent to 25 percent potassium oxide.

In late 1963 the Parsons Co. began geological exploration of the Dallol concession for other minerals; all of these minerals, except oil and hydrocarbons, are included within the rights granted the company.

Salt.—The salt production comes mainly from the solar evaporation of the Red Sea waters by Società Saline di Massaua and Société des Salines d'Assab. Each installation has a capacity of about 100,000 metric tons. In 1963 the Massaua company expanded production; this accounts for the increased output. Of the total, about 20,000 tons

[7] Potash Developments in Ethiopia. Overseas Geology and Mineral Resources (London). V. 9, No. 3, 1964, p. 324.

Digitized by Google

was rock salt, quarried in the depression area near Dallol by Dedjazmach Menghesha Seyoum and sold in traditional local markets.

MINERAL FUELS

Petroleum.—Gewerkschaft Elwerath of Hanover, West Germany, continued geophysical work within its 90,000-square-kilometer concession, formerly held by Sinclair Oil Co. and granted to Elwerath for 50 years. Deep drilling of favorable structures began with the first well, started on June 28, at Abred in the Ogaden area near the Somaliland frontier. Total expenditures to June were estimated at Eth$12.9 million.

On February 14, the Ethiopian Government signed an agreement with Mobil Petroleum Co., Inc. This agreement provides for Mobil's exploration for crude oil, natural gas, and associated hydrocarbons in and on the coastline, coastal islands, and offshore area of the Red Sea north of Massawa. The concession, valid for 50 years, covers more than 27,000 square kilometers and will gradually be reduced to 7,000 square kilometers. If production results, the government will receive annual payments by way of rental, royalty, and taxes, equal to 50 percent of Mobil's profits from its production venture. A new subsidiary was established, Mobil Petroleum Ethiopia, Inc., and geophysical work was expected to commence later in 1963.

A petroleum agreement also was signed by the government on November 14 with the Gulf Oil Co. of Ethiopia, a subsidiary of Gulf Oil Corp. The agreement grants to Gulf rights to explore for petroleum in an area of approximately 28,00 square kilometers in the Red Sea and along the coast of Massawa, south and southeast of the Mobil concession area. The terms of the Gulf agreement were made public only in the most general sense.

On November 14, an agreement was signed between the government and Mobil Oil (East Africa), Ltd., for the construction of bunkering facilities at the port of Assab. Work was scheduled to begin immediately and to be completed about August 1964. Bunkering facilities will be available for six ships at a time.

In August 1962 the Ethiopian Government contracted with the U.S.S.R. for the erection of a refinery at the port of Assab, to be completed by 1966 and have an annual capacity of 500,000 metric tons of crude. The project was expected to cost Eth$37.5 million, of which Eth$20.5 million was to be loaned by the U.S.S.R. Construction for housing for the Soviet construction crews began in March, and erection of the refinery was scheduled to begin later in the year. According to September newspaper reports, the refinery is being designed for Kirkuk crude with flexibility to cover most Middle East crude. It reportedly will be supplied by crude from any country, depending upon all relevant factors such as competitive prices, marketing conditions, and suitability.

Data on consumption of fuel are not available; it undoubtedly approaches imports rather closely, and bunker deliveries to all flags are estimated to have comprised about 8 percent of total consumption. The virtual termination of imports of coal and coke in 1962 indicates replacement of these by oil and electric power; production of the later by public utility companies, exclusive of those in Eritrea, was 29 percent higher in 1962 than in 1961.

The Mineral Industry of Gabon

By Thomas G. Murdock[1]

THE MINERAL industry of the Republic of Gabon became considerably important with the spectacular 1963 increase in production and exports. Significant features of the year were the: Bringing into full production of new manganese mines; discovery of additional offshore petroleum deposits, resulting in a 100-percent increase in the known reserve; and doubling of gold production and exports over 1962 figures.

While only the 1963 manganese production was of world importance, corresponding to 4.5 percent of 1962 world output, increased quantities of other minerals greatly improved the national economy and uranium production again constituted an important source of supply for France.

The 1963 mineral production, exclusive of building materials, was valued at CFAF8,589 million (US$35.06 million);[2] of this manganese ore comprised CFAF3,500 million and crude petroleum CFAF2,700 million. The 1962 gross national product was CFAF22,050 million and in that year the mineral production, valued at approximately CFAF5,630 million, contributed 25.5 percent of the GNP. This rose in 1963 when timber exports, the most important source of Gabonese income, failed to maintain the steady upward growth necessary to support the expanding investment program of the country.

Latest available data on employment by the Gabon mining industry are for 1956 when 6,146 indigenous employees were engaged in this activity and comprised 5 percent of the available manpower. The extensive subsequent developments, particularly in the production of gold as an activity of numerous individual small-scale miners, have probably more than doubled employment in the extractive industries.

No new U.S. participations in Gabon mineral developments were recorded in 1963, and at yearend they consisted of the 49-percent interest of United States Steel Corp. in the manganese mining company, 50-percent share of Bethlehem Steel Co. in the company that explored the Mekambo iron-ore deposits, and an association of Mobil Oil affiliates with the French petroleum company active in the country. A New York firm was awarded the US$2.5 million contract for feasibility studies of the construction of a railway to serve the iron-ore field.

GOVERNMENT POLICIES AND PROGRAMS

In 1962 a new mining code was published. The only recorded 1963 change to this was the prohibition of alluvial gold and diamond mining to all persons except those of Gabonese origin who are working as registered artisans under the direct control of the Government company, Société Gabonaise de Recherche Minière (SOGAREM), established in 1962 to expand mineral production. This company achieved marked success in its first year, effectively doubling the gold output.

Exploration activities were carried out by SOGAREM, the oil companies, and the French Bureau de Recherches Géologiques et Minières (BRGM). The latter organization discovered a large body of argentiferous lead ore in the Mandji area, explored columbium-tantalum deposits near Tchibanga and near Eteke, and endeavored to develop a new technique of prospecting for diamonds in an area where they were formerly produced.

The Government of Gabon made progress carrying out the 3-year plan, covering the 1963–65 period, which was adopted by the national legislature at the end of 1962. This plan set forth major goals to be obtained before inauguration of a more comprehensive 5-year program of economic development. The Government continued its significant efforts to encourage the inflow of foreign private investment, having enacted a favorable Investment Code on November 8, 1961. An Investment Guarantee Agreement with the United States was signed in April 1963.

SOURCE MATERIAL

Background information on the country was provided by a comprehensive U.S. Government publication.[3] Production data and an account of 1963 developments are from the dispatches of the U.S. Embassy, Libreville, supplemented by the technical press.

PRODUCTION

The outstanding performance of the extractive industries is best indicated by comparing 1963 production with that of 1960. Apart from the establishment of significant production of two new commodities, manganese ore and uranium concentrate, the other items have shown a substantial overall growth, despite shortfalls in some individual years. The 1963 value of production of items recorded was 283 percent more than that of 1960. The quantities of building materials produced are not known, as data apparently are not collected; indications are that except for lime and cement requirements of the country are met by domestic production and while these needs have not shown phenomenal growth like the metals and fuels, output in 1963 was undoubtedly above that of the immediately preceding years.

Petroleum, crude.....thousand tons..	753	800	774	827	890

[1] In addition, building materials other than cement and lime are produced but no quantitative data are available.

TRADE

In 1962 the total value of metal and mineral imports was CFAFr1,313 million, 13 percent of all imports, compared with CFAFr1,037 million and 12 percent in 1961. The 1962 import value by categories was: Metals, CFAFr514 million; nonmetals, CFAFr263 million; and mineral fuels, CFAFr536 million. Exports were valued at CFAFr5,199 million (CFAFr3,565 million in 1961) and were composed almost entirely of crude petroleum (CFAFr2,527 million), uranium concentrates, (CFAFr2,193 million), manganese ore (CFAFr371 million), and gold (CFAFr93 million).

France continued to be the principal partner of Gabon in metal and mineral trade in 1962, supplying 62 percent of the imports and receiving 94 percent of the exports. The Netherlands Antilles and Venezuela, suppliers of most of the petroleum refinery products, ranked second and third, respectively, among the suppliers, with the United States ranking fourth with 4 percent of the imports. The European Common Market, of which Gabon is an associate member, supplied a total of 67 percent of all imports. The United States ranked second as a customer, receiving 2 percent of all metal and mineral exports. Imports of this category from the United States, mostly petroleum refinery products, comprised 5.8 percent of all imports from that country; mineral exports to the United States were exclusively of manganese ore and their value was 25 percent of all Gabon exports to that destination.

Based on the first quarter value of imports of principal commodities, 1963 imports may be roughly estimated at CFAFr1,297 million. Preliminary figures of value of exports for the year indicate that this rose to CFAFr7,718 million, with the greatly expanded shipments of manganese ore accounting for the increase.

COMMODITY REVIEW

METALS

Gold.—The phenomenal increase in gold production was the result of efforts to expand exploitation of the alluvial and eluvial deposits on a small-worker basis, organized by the Government SOGAREM. This company, created in late 1962 and intended for the promotion of mineral exploration and production in general, concerned itself particularly with gold. It acquired the holdings and installation of the ORGABON-MICONZOU Group and made a lease agreement with

Digitized by Google

the Compagnie Minière du Nord-Gabon, thus obtaining an effective monopoly in gold production. The SOGAREM position was strengthened additionally by the decree of November 16, 1963, when the Government declared the country closed to further exploitation of its alluvial gold resources by all persons except those of Gabonese origin who are working as registered artisans under the direct control of the company. This decree was issued mainly to prevent non-Gabonese possessing gold-mining concessions from hiring local villagers at low wages to do the work and then reaping substantial profits by selling the metal to the Government, which purchases all gold found in the country at CFAF6,221 per ounce. Some of the artisans have found gold-mining quite lucrative, and individual monthly earnings as high as CFAF100,000 have been reported. Production mainly came from the Districts of M'Bigou, Koula-Moutou, N'Djole, and Lastourville; a new deposit discovered in the latter area was in part responsible for doubling production. SOGAREM concentrated on exploitation of alluvial and eluvial deposits but is scheduled to explore and exploit the lodes.[4]

Iron Ore.—Following the 1962 announcement that the overall iron ore reserves at the Mekambo property of Société des Mines de Fer de Mekambo (SOMIFER) in northeast Gabon amounted to 860 million metric tons, averaging 64 percent iron, a series of studies concerning the economic development was inaugurated during 1963. SOMIFER is a consortium of American and Common Market steel companies in which Bethlehem Steel has a 50-percent interest and has managed operations in Gabon. The 1963 studies were concerned with construction of about 700 kilometers of railroad, probably to the port of Owendo near Libreville, and with port equipment. These studies received financial and technical support from the United Nations Special Fund, the World Bank, and the European Development Fund. Foley Brothers of New York was engaged to conduct the railway study and began on-the-ground work in July. Expectations in late 1963 were that enough information should be available in 1965 for the economic feasibility of the whole Mekambo project to be assessed.

Exploration of other areas for iron ore was carried out during the year by the French Bureau de Recherches Géologiques et Minières (BRGM) in cooperation with the High Authority of the European Coal and Steel Community. This work included aerial magnetometer surveys, and encouraging anomalies were reported; however, these had not been fully investigated, and the program was scheduled to continue.

Manganese Ore.—October saw completion of the first year of full-scale operations at the Moanda manganese mine of Compagnie Minière de Igooúe (COMILOG), major economic asset of Gabon. Capitalized at CFAF25 billion, 49 percent subscribed to by United States Steel, COMILOG has invested Fr24 billion in opening the large deposits—having reserves of about 200 million metric tons of ore, containing an average of 50 percent manganese. Extraction and beneficiation of the ore presented no special problems. Mining continued to be carried out on the Bangombe plateau, where ore in beds

[4] Mining Journal (London). V. 261, No. 6687, Oct. 18, 1963, p. 354. Annales des Mines (Paris). April 1964, p. 61.

Digitized by Google

4 to 6 meters thick with only a thin waste capping was stripped and mined by conventional open-cut methods. After crushing, washing, and screening the marketable product had a typical analysis of 50 to 52 percent manganese, 3 to 4 percent ferric oxide, 2 to 3.5 percent silica, 6 to 7 percent alumina, and 0.10 to 0.13 percent phosphorous. Evacuation of the product is over the 76-kilometer aerial tramway to M'Binda on the Gabon-Congo frontier and thence through Congo (Brazzaville) to Point Noire on the Atlantic Ocean, 285 kilometers of newly constructed railway and 200 kilometers of the Chemin de Fer Congo-Ocean, which runs from Point Noire to Brazzaville.[5]

COMILOG continued work on installation of a concentration plant to produce an ore enriched to nearly 85 percent of dioxide or 56 percent manganese. This installation was scheduled for completion in July; capacity was to be 40 tons of concentrate per shift, or about 10,000 metric tons per year. It was planned with a view to possible further extension.

Despite the highly competitive situation of the world manganese market and a 32-percent drop in world market price since the inception of COMILOG in 1963, 1963 exports, based on preliminary figures, for shipments from Point Noire through December 13, were more than 90 percent of the production, totaling 575,000 metric tons consigned as follows: United States, 355,000 tons; France, 108,500 tons; West Germany, 77,500 tons; Japan, 29,000 tons; Spain, 3,000 tons; and Italy, 2,000 tons. The impact of the new supply on the world market has been reflected in the decreased output of other countries, particularly Morocco.

Uranium.—Expanding uranium production continued to come entirely from the Mounana deposits in remote southeastern Gabon. Founded in 1958, Compagnie des Mines d'Uranium de Franceville (CMUF), capitalized at CFAF2.5 billion, had an estimated reserve of 25 million metric tons of ore expected to yield about 5,000 tons of uranium metal. The capital is held by the French Atomic Energy Commission, several private French mining interests, and several French banks. Company production was guaranteed by special agreements between Gabon and France under which all sales of CMUF are to France. The Mounana mine has provided an estimated one-quarter of French needs in its first years of operation. Production of ore has been by open-pit methods at about 14,000 metric tons per month, but this will be replaced by underground working by 1966; during 1963 sinking of a 200-meter hoisting shaft continued. The treatment plant handled increased production; separation was effected by a sulfuric acid leach, followed by precipitation in a magnesia bath, filtration, and drying. Concentrate is shipped to Point Noire by rail; exports are reported at 1,300 tons of concentrate, containing 30 percent uranium oxide. A sulfuric acid plant was reported under construction at the beginning of the year and indications were that this was continued during 1963. The French Atomic Energy Commission proposed investigation of the Lastourville area, which had not previously been prospected for uranium.

NONMETALS

Cement.—In December a contract was signed for construction of a cement plant near the port of Owendo, following discovery of commercially exploitable deposits of limestone on the Isle of Coniquet in the Gabon Estuary. The contract created Société des Ciments Portland Gabonais, capitalized at CFAF300 million, of which the Gabonese Government will hold 80 percent. The plant, which is expected to supply the local market of approximately 40,000 tons annually and eventually a small export market, is expected to cost about CFAF980 million.

MINERAL FUELS

Petroleum.[6]—Because the onshore Gabon structures are highly faulted, and wells have been of only a short life, the year saw a continuing emphasis on offshore exploration; significant new discoveries were reported from the Anguille region near Port Gentil. Anguille offshore production in 1962 accounted for about 9 percent of the total in that year; it contributed effectively to the 1963 increase, and in May two wells in the area were yielding together 350 tons per day. New discoveries raised the hopes of the Gabonese Government for a sustained growth in production. The total reserve, placed at about 10 million tons at the end of 1962, was reported to have doubled with the 1963 finds.

Société des Pétroles d'Afrique Équatoriale (SPAFE), controlled by the French Government but with small participation from the four States of ex-French Equatorial Africa (Gabon, Congo, Central African Republic, and Chad), continued exploration and production within its holdings totaling 105,934 square kilometers. This area includes four offshore permits. SPAFE continued its association in some permits with the Shell group as Compagnie Shell de Recherches et d'Exploitation au Gabon (COSREG) and with the Mobil Group as Mobile Exploration Equatorial Africa (MEEA). Participation of the latter companies varied for individual permits. For onshore associated holdings, one covered 5,275 square kilometers in which SPAFE and COSREG each had equal shares and COSREG was the operator; the other covered 12,045 square kilometers with SPAFE holding 50 percent and the remainder divided between MEEA and Mobilrex (another Mobil affiliate), in which SPAFE was the operator. Mobil and SPAFE share equally in the 4,335 square-kilometer-permit offshore of Port Gentil, Mobil being the operator; this arrangement was also applied within the 2,010 square-kilometer-permit offshore of Mayoumba, and the Sette Cama offshore permit was shared equally between SPAFE and COSREG with the latter carrying out the work. In October, Offshore International, an American company, was participating in exploratory drilling on a contractual basis on the offshore areas of the Mobil-shared concession of which the Anguille field is a part.

The Gabon producing fields extend 150 kilometers along the coastal zone south of Libreville to the south of Port Gentil. SPAFE is based

[6] Industries et Travaux d'Outremer (Paris). V. 11. No. 121, December 1963, p. 1031. World Oil. V. 157. No. 3, Aug. 15, 1963, pp. 162–164.

Digitized by Google

on the Cape Lopez field, near Port Gentil. Production by field is not available, but except for the increased output from Anguille it is estimated to have been about the same as in 1962, when the following distribution was reported for the four major fields: Tchengue, 203,695 tons; Pointe Clairette, 175,209 tons; M'Bega, 142,879 tons; and Cape Lopez, 121,267 tons. The 1962 production of the smaller fields was approximately as follows: Batanga, 91,127 tons; Ozouri, 46,501 tons; Animba, 14,876 tons; Rembo Kotto, 9,485 tons; Simany, 8,208 tons; Anguille (offshore), 7,693 tons; Alewana, 4,503 tons; and Illigoue, 1,487 tons. In 1963 drilling of 13 wells was completed, a decrease from 1962 when 27 wells were completed, including 17 dry ones, and their aggregate depth was 48,068 meters. At the beginning of 1963 production was from 64 wells, 21 of which were with artificial lift. Most of the fields continued to be served by the 90-kilometer pipeline between Cape Lopez and Ozouri; a 40-kilometer line connects the Rembo Kotto with Lake Odombo.

Expenditures of SPAFE for exploration, in 1962, including those in the Congo (Brazzaville) where this company has extensive holdings, were reported at CFAF2.5 billion. Cumulative sales of Gabon production through 1962, more than CFAF12 billion, were less than the total investments of SPAFE and its associates in the country.

At yearend agreement in principal for construction of a refinery to serve Gabon, its partners in the Equatorial Customs Union (Congo-Brazzaville, Central African Republic, and Chad) and nearby Cameroun had been reached by the respective governments, although the final decision as to location was still pending. A few weeks later it was announced that this facility, to have an annual capacity of 700,000 metric tons, would be built at Port Gentil.

Natural Gas.—The slight drop in natural gas marketed was the result of SPAFE's decreased deliveries to the only customer, Société d'Energie Electrique de Port Gentil, the company that provides the Port Gentil electric power. The latest data on gas reserves are for the end of 1961 when Gabon was credited with a total of 8,495 million cubic meters.

The Mineral Industry of the Republic of Ghana

By Thomas C. Denton [1]

FOLLOWING the pattern of many years, Ghana's significant mineral production in 1963 besides construction materials consisted of gold, diamond, manganese ore, and bauxite in that order for value. Rank in world production of these minerals in 1963, exclusive of Communist countries, was 5th after Australia for gold, 3d after the Republic of South Africa for diamond, 6th after Republic of Gabon for manganese ore, and 13th after Italy for bauxite. Available information indicates that bauxite outranks the others in quantity of reserves. Four areas in which it occurs contain deposits with an aggregate reserve of at least 200 million tons.

The minerals named were produced by Ghana for export, and generally account for nearly 99 percent of the total value of mineral exports. Their position in the domestic economy was important in contributing to badly needed exchange earnings, contribution to gross national product and employment, and for the training of Ghanaians for skilled and supervisory positions provided by all expatriate mining companies.

Mineral exports in 1962 contributed 22.4 percent of the total value of domestic exports and were about 4.7 percent of estimated gross national product (US$1.484 billion in 1962).[2] The mineral contribution to exports in 1961 was 21.8 percent. Gold bullion provided 44.7 percent of the mineral value in 1962; diamond 29.6 percent; manganese ore 21.6 percent; and bauxite 2.7 percent.

As for employment and training,[3] gold mines were employing 20,086 Africans and 555 non-Africans; manganese mining, 2,411 Africans and 40 non-Africans; diamond mining companies, 4,506 Africans and 120 non-Africans; African diamond industry, 5,250 Africans; bauxite mining, 447 Africans and 16 non-Africans as of March 31, 1962. In addition, there were 376 Africans and 22 non-Africans engaged in prospecting. Since the year covered by the report, the non-Africans employed has decreased significantly as the result of efforts by the Government and companies to Africanize industry to the maximum.

Thus, mining companies in Ghana both operate well-equipped trade schools on their properties and finance technical education of Ghanaians abroad.

During the first half of 1962 Soviet technicians and equipment arrived to begin implementation of a geologic survey of northern Ghana. In addition, steps were taken to build 64 houses for Soviet technicians at Tamale, and the Ghana Government assigned 230 Ghanaians to the Soviet team.[4] This activity continued throughout 1963, and arrangements were made for Soviet mineral technicians to assist the Ghana Geological Survey upon its request.

In September 1963, when the Survey celebrated its 50th birthday, the Director announced plans for projects designed to evaluate and exploit iron ore and bauxite deposits. Development of the bauxite and subsequent domestic production of aluminum from it would be the most important project in the Ghanaian program for mineral development.[5]

GOVERNMENT POLICIES AND PROGRAMS

In October a substantial increase in the withholding tax on profits remitted home by foreign companies was announced. Also in October the budget for the fiscal year ending September 30, 1964, was introduced, which increased expenditures 12.5 percent and appeared to make another large budget deficit inevitable. Economic services, including fuels and power, and mining and manufacturing were allocated 29 percent of a total budget of 144 million Ghana pounds (G£).[6] On the Volta River Project G£7 million was to be spent.

New revenue measures introduced which directly and indirectly bear on mineral industry included: (1) increased taxes on gasoline, kerosine, diesel and fuel oil; (2) increases up to 25 percent on vehicle registration and driving licenses; (3) increased purchase taxes on commercial vehicles; (4) increased postal rates; (5) a new 5-percent excise tax on locally manufactured goods, including boots, paints, etc.; (6) users tax on all airline tickets; (7) an annual registration fee for importers of from 50 to 200 G£; (8) a fee of 1 percent of value on all import licenses.

In addition, income taxes would be collected by the employer, and the employer was to withhold tax on all wages and salaries of G£11 and over per month at rates ranging from 6 to 32.5 percent. Company income tax was increased. The compulsory savings scheme which had been in effect since 1961 was abolished. The Government, according to reports, expected to more than compensate for the loss resulting from the action by the increases in income tax.[7]

A bill to establish an Atomic Energy Commission was introduced in November. Provisions of the bill included: (1) That the Commission, whose members the President would appoint, would be solely responsible for all matters relating to the peaceful use of atomic energy in Ghana, including relations with the International Atomic Energy Agency and arrangements with other African countries for conduct-

ing atomic energy research; (2) that the Commission would establish an institute to be called Kwame Nkrumah Nuclear Research Institute, which on behalf of the Commission would be responsible for the supervision, control, and operation of any nuclear installation in Ghana.[8]

SOURCE MATERIAL

The annual reports of companies operating in Ghana were particularly useful in preparing the chapter. Other source materials were articles appearing in trade journals, publications of the Government of Ghana and dispatches of the U.S. Embassy in Accra.

PRODUCTION

It seems unlikely at the present time that the existing pattern of Ghana mineral industry will change to an important degree in the immediate future insofar as raw mineral output is concerned. But the outlook for transforming industry is more encouraging. Besides an aluminum reduction facility, an iron and steel plant with rolling facilities is to be built for which at first the iron raw material will be scrap. In addition, semifabricating facilities for aluminum are being expanded, and cement and glass manufacture is to be undertaken.

[1] Estimate.

TRADE

Despite its dependence on imports for energy, Ghana has a favorable balance of trade in minerals (including minerals, mineral fuels, metals, and semimanufactures of mineral origin). The position results from very substantial gold production. In 1962 the value of mineral imports was G£17.4 million, whereas exports were G£25.1 million, of which gold bullion was 44.7 percent. Bullion went to the United Kingdom for refining, and in 1962 the United Kingdom also received most of the diamond exported, thus being the major recipient of Ghana mineral exports by value that year.

[8] Source cited in footnote 7.

Digitized by Google

By value about 41 percent of imports in 1962 were refined petroleum products, and 29 percent were iron and steel semimanufactures. Establishment of a refinery in Ghana late in 1963 was expected to result in a sharp decline in imports of petroleum refinery products.

COMMODITY REVIEW

METALS

Aluminum.—The Volta River Authority announced at yearend that the dam and powerplant at Akosombo were half completed and that all phases of the project were on schedule. The main dam was expected to be constructed to an elevation of 260 feet by October 10, 1964, so as to avoid possible damage during the 1964 flood season. Behind the dam an 8,482-square-kilometer lake will form. It will be necessary to remove 80,000 people from the area.

Work on the power transmission grid was estimated to be 13 percent complete at yearend. Power was expected to be available by September 1965. About half the power generated at Akosombo at the outset will be consumed by a US$144 million aluminum reduction plant which Volta Aluminum Co. (VALCO) will build and operate at Tema, the new artificial port in Ghana. Work on the plant was expected to begin in June 1964. Alumina for the facility will be imported. VALCO is owned 90 percent by Kaiser Aluminum and Chemical Corp. and 10 percent by Reynolds Metals Co. Loans to VALCO were extended by the Agency for International Development and Export-Import Bank of the United States.[9]

Bauxite.—In 1963 British Aluminum Co., Ltd. (BAL), 47.7 percent owned by Reynolds Metals Co., was the only producer of bauxite and it has been since 1941, when it began exploiting Ghana bauxite at the instigation of the then British Ministry of Aircraft Production. Exports at 210,752 metric tons were lower than in 1962 by nearly 28 percent but only 2.4 percent lower than average annual exports for the period 1959–63. Most exports were to the United Kingdom. The BAL operation in Ghana has been for many years a major source of bauxite for the small primary aluminum industry of the United Kingdom. BAL is interested in a Canadian producer of primary aluminum, Canadian British Aluminium Co., Ltd., whose plant was opened officially in 1958. BAL exports in 1962 included nearly 12,000 tons to Canada, presumably for the Canadian British company.

The BAL output was from an open-pit operation at Kanayerebo in the Western Region, from which the bauxite was trucked to railhead at Awaso. Numerous additional deposits are known and the indicated aggregate reserve of four bauxite areas in Ghana is more than 200 million tons with average alumina content of about 47 percent.

Gold.—Ashanti Goldfields Corp., Ltd., continued to contribute nearly 50 percent of gold output. Ashanti expanded operations and was largely responsible for the increase in total Ghana production to a new record output for the country valued at US$32.2 million in 1963. The other contributors were the Government-owned Ghana State Mining Corp. and Konongo Gold Mines, Ltd. Konongo, which had expected to exhaust its ore reserve by September 1963, found additional ore while exploring the footwall by diamond drilling.[10]

In April the Ghana Geological Survey announced plans designed to increase the annual gold production of the country by 200,000 ounces by 1965. The scheme included prospecting the Tano, Offin, Pra, and

[9] Except for statement about source of alumina for the plant, source cited in footnote 7.
[10] Page 14 of source cited in footnote 7.

Digitized by Google

Ankobra Rivers and their tributaries and dredging many smaller rivers believed to contain rich alluvial deposits. The scheme also included: (1) Persuading existing underground mine operators to increase production by 25 percent; (2) increased dredging of gold from small alluvial flats; (3) using small mobile equipment to work small gold prospects.[11]

Ashanti Goldfields Corp., Ltd.—On a concession situated at Obuasi, this British-owned company incorporated in the United Kingdom in 1897 has one of the richest large gold mines in the world. Operating costs, however, are exceptionally high for a mine of its size, in part because of heavy ground—much of which must be square set.

The following information regarding the Ashanti operation is for the year ended September 30, 1963.

Gold production at 444,251 ounces recovered from 468,139 short tons of ore milled (0.9489 ounces or US$33.21 per ton) was again a record, and during August the 10-millionth ounce of gold was produced. Operating expense in Africa excluding development totaled £2,315,566, equivalent to £4 19s. or US$13.86 per short ton milled. Development expenditures were £291,477, equivalent to 12s. 5d. or US$1.74 per ton milled. Total costs per ton milled thus were £5 11s. 5d. or US$15.60. In terms of gold, these cost figures are equivalent to 0.446 ounce, which compares with 0.207 ounce reported by the Transvaal and Orange Free State Chamber of Mines as "the average working costs" of 55 gold mines of the South African Rand in 1962.

The ore reserve on September 30, 1963, was 2,990,000 short tons, averaging 1.0925 ounces gold per ton; the value represented also was a new record. In addition, development results during the year continued to be excellent.

Profits for the year before taxes exceeded £2 million for the first time in the history of the mine. Dividends nevertheless had to be reduced from 2s. per share paid the previous year, to 1s. 6d. or by 25 percent. The action was necessary because the Ghana budget, introduced in August 1963, sharply increased both taxes and operating costs. Total taxes, duties, and compulsory savings amounted to 77.3 percent of profits for the year. Beginning in October 1963 Ashanti officials discussed alleviation of the situation with Ghana authorities. If the tax burden were reduced, Ashanti could advance its plans for still larger production.

Ghana State Mining Corp. (GSMC).—GSMC was incorporated March 1, 1961, by an instrument signed by the President of the Republic on March 4, 1961. It was formed to purchase the outstanding shares of five companies in the United Kingdom operating gold mines in Ghana and to exercise overall management of the operations. After more than 90 percent of shareholders had accepted its offers, GSMC bought the shares for G£5,165,550, which was reported as reasonable. The purpose of GSMC was to save the jobs of some 14,000 workers after the companies had declared their intention of abandoning the mines as unprofitable.[12]

The following companies were purchased:

Amalgamated Banket Areas, Ltd. (ABA).
Ariston Gold Mines (1929), Ltd. (Ariston).
Bibiani (1927), Ltd. (Bibiani).
Bremang Gold Dredging Co., Ltd. (Bremang).
Ghana Main Reef, Ltd. (GMR).

The most recent available information on ore reserves of these companies and their gold production during the first quarter of 1963 is as follows:

	Ore reserves			Production 1st quarter of 1963, ounces
	Short tons	Average gold content, ounces/ton	Date of reserve calculation	
ABA	491,569	0.2699	Sept. 30, 1961	27,789
Ariston	1,298,558	.3465	----do----	30,468
Bibiani	494,000	.2275	----do----	15,857
Bremang	[1] 77,148,900	[2] .266	Dec. 31, 1961	16,242
GMR	235,895	.4295	June 30, 1961	13,527
Total	----------	------	----------	103,883

[1] Cubic yards.
[2] Grains per cubic yard.

During 1963 GSMC amalgamated Ariston and Ghana Main Reef, improving financial results somewhat.[13] For the fourth quarter of 1963 the corporation reported slight declines in output from all its mines except Bremang, where production and profits continued to increase. Purchase by the corporation of the privately owned Konongo gold properties reportedly was still under consideration.[14]

Manganese Ore.—The only producer of manganese ore in Ghana was the British company, African Manganese Co., Ltd. (AMC), owned by Union Carbide Corp. of the United States. This has been the situation for many years, except that nominal tonnages have been produced sporadically by others.

Besides metallurgical ore AMC produces manganese ore used for dry cell battery manufacture and by chemical industry, which is widely accepted. In recent years ore identified as containing not more than 30 percent manganese has also been produced.

Ghanaian exports of manganese ore in 1963 were 394,091 metric tons valued at G£4,015,808, compared with 472,287 tons valued at G£5,419,760 in 1962. The 1962 tonnage by grades and value was as follows:

	Metric tons	Value G£
Battery grade	28,513	925,166
Containing more than 30 percent Mn	437,438	4,438,121
Containing not more than 30 percent Mn	6,336	56,473

Most of the battery-grade ore went to the United Kingdom and the United States, the former taking about 40 percent; the latter, 39 percent. There were four additional recipients.

NONMETALS

Diamond.—Of the order of 80 percent of the diamond produced in Ghana is industrial diamond; mostly the stones are small, few weigh-

[13] Mining Journal (London). Annual Review. June 1964, p. 199.
[14] Source cited in footnote 7.

Digitized by Google

ing more than 1 carat. The industry is principally in the hands of many individuals and small groups called diggers and one company, the United Kingdom company, Consolidated African Selection Trust, Ltd. (CAST). Company operations are highly mechanized, while diggers largely use primitive methods. Nevertheless, until recently, aggregate digger production has exceeded CAST production. The combined output of diggers and organized operations in 1963 was 2,677,820 carats—530,238 carats less than in 1962.

All Ghana diamond must be sold to the Ghana Diamond Marketing Board, established by the Government on January 1, 1963, as the sole legal purchaser, valuer, exporter, and seller of diamonds mined in the country. Sales by the Board in 1963 continued at a level substantially below that of previous years with consequent major losses of foreign exchange. Exports by the Board during the period January–November 1963 were 1,434,518 carats, valued at G£3.11 million, compared to 3,067,716 carats, valued at G£6.64 million in the same period of 1962. Observers attributed the decline to inconsistent pricing policies of the Board that tended to inhibit producers from selling to the Board.[15]

Toward the end of the year the Board took measures to improve the situation. The measures included establishment of two diamond buying centers in the country besides Accra. It was hoped that the Board actions would attract a greater proportion of diamond production into legitimate channels of the diamond trade.[16]

Digger Operations.—Digger operations are supervised by the Department of Mines of Ghana, which in its annual reports totals exports of diamond by holders of digging licenses and prospecting licenses. The report for 1962 shows that during the period 1956–59 such exports increased steadily, reaching 1,844,282 carats, valued at G£4,990,000, in 1959. Thereafter, exports of diamond won by diggers decreased to 1,187,548 carats, valued at G£3,124,315, in 1962. A further decline was indicated for 1963.

The Mines Department also reported that 236 digging licenses were issued in 1962, of which 91 were issued to Ghanaians and 145 to non-Ghanaians. The majority of the latter were Yorubas from the Western Region of Nigeria.

Consolidated African Selection Trust, Ltd. (CAST).—The company announced plans to invest G£3 million during the next few years. A new large plant was to be built, existing plant and equipment were to be modernized, and additional welfare facilities were to be provided for employees.[17]

For the year ended June 30, 1963, CAST reported in part as follows regarding its operations in Ghana:

	1963	*1962*
Diamond produced, carats:		
From gravel	1,739,574	1,776,621
From sundry residues	73,163	134,373
Totals	1,812,737	1,910,994
Gravel treated, cubic yards	1,010,450	907,650
Overburden removed, cubic yards	567,660	467,145

[15] Source cited in footnote 7.
[16] Mining Journal (London). Dec. 20, 1963, p. 599.
[17] U.S. Embassy, Accra. Economic Summary, January–June 1963, p. 4. Airgram A–166, Sept. 26, 1963

Digitized by Google

The increase in quantity of gravel treated resulted from the start of production at No. 8 plant in January together with additions to throughput at Nos. 10 and 11 plants. Design and ordering of equipment for the new treatment plant (No. 12) to be erected adjacent to Nos. 10 and 11 plants were well advanced. Construction of the plant was scheduled to begin in March 1964 with completion expected early in 1965.

Prospecting and development continued to yield satisfactory results. Major emphasis was on full development of deposits indicated by reconnaissance prospecting conducted in previous years.

Total overall cost per cubic yard treated again declined slightly in spite of continuation in the general upward trend in cost of supplies.

Profit for the year at £1,310,000 was £310,000 less than in the previous year. Although a larger volume of diamond was sold, the average price fell, partly due to market conditions, partly to the commission or profit retained by the Government Marketing Board, and partly to inclusion of the smaller, less valuable diamond recovered by treatment of concentrator house residues. At the end of the year a satisfactory method of determining prices to be paid CAST by the Diamond Marketing Board had not been determined.

CAST operations continued to benefit from personnel training programs introduced earlier. Three plants were being supervised by Ghanaian engineers.

MINERAL FUELS

On September 28, 1963, President Kwame Nkrumah of Ghana formally opened the first oil refinery in West Africa, at Tema about 27 kilometers east of Accra, the Capital. Ghana-Italian Petroleum Co., Ltd. (GHAIP), a subsidiary of the Italian State-owned Ente Nazionale Idrocarburi (ENI) will operate the refinery. It has an annual processing capacity of 1,250,000 tons and can produce premium and regular grade gasoline, fuel oil, and liquefied petroleum gas.

GHAIP will transfer free 50 percent of its authorized equity capital of the equivalent of US$9,520,000 to the Ghana Government on the 11th anniversary of the beginning of production. The Government also will receive 50 percent of profits, will appoint the chairman of the board of directors of GHAIP and one-half of its membership, and will have the final say in determining prices at which products will be sold.

The refinery, which went on stream in July, was processing about 4,000 tons of Nigeria crude per day. Under an agreement signed in September, the oil companies already marketing petroleum products in Ghana were to supply crude oil to GHAIP in proportion to their market requirements and withdraw an equivalent amount of refined products.[18]

Soviet equipment and instruments for oil exploration were included among material which Ghana would purchase from the U.S.S.R. as a result of the technical assistance agreement of August 1960 and a credit of the equivalent of US$40 million provided by the U.S.S.R. In March 1962, 25 Soviet geologists arrived in Accra for a 2-year geological survey of the country.[19]

The Mineral Industry of Guinea

By Thomas G. Murdock [1]

GUINEA'S 1963 mineral production showed a slight decline over that of 1962. This decline was indicated by export data; complete 1963 mineral production data are not available. The achievement of full-capacity plant production of alumina from local bauxite was an important event for the only facility of this kind on the African Continent and Guinea's principal industrial establishment. The year was also noted by progress toward an expansion of production of the few minerals mined there: An agreement was signed with an American company for the development of the extensive bauxite deposits, prospects improved for the sale of Guinean iron ore and the opening up of new iron ore deposits, and diamond mining by private companies and entrepreneurs was encouraged in a part of the country.

Guinea is important in the world mineral economy only as a producer of bauxite and alumina. In bauxite production the country ranked seventh and contributed about 5 percent of the world total. With at least 16 percent of world bauxite reserves, its standing is greatly enhanced.

The 1962 mineral and metal production, exclusive of building materials, had an estimated value of GFr8,342 million (US$33.77 million).[2] The 1962 gross national product (GNP) was GFr48,412 million, thus in that year minerals and metals contributed about 17 percent of the GNP.

Few data on employment by the industry are available. At the beginning of 1963, bauxite mining and processing employed 936 Africans and 412 European expatriates. Employment in iron mining probably did not exceed 300 Africans and 40 Europeans. A larger labor force was believed engaged in diamond prospecting and mining, and this may have been in the order of several thousands. Regardless of actual number employed in mining and processing, the proportion of the total labor force is small; about 90 percent of the estimated 3.4 million inhabitants are engaged in agriculture.

U.S. investments in the Guinean industry consisted of the participation of Olin Mathieson Chemical Corp. as the largest shareholder in the existing bauxite to alumina complex, an association of Harvey Aluminum Inc., and the Guinean Government in the development of additional bauxite deposits, and one of United States Steel Corp. and Jones & Laughlin Steel Corp. in an international consortium for opening up large iron ore deposits.

GOVERNMENT POLICIES AND PROGRAMS

The year 1963 saw a continuation of the 1962 trend toward an orientation of Guinea's commercial relations back toward the West and a demonstration of the recognition of the role that private capital could play in the development of the economy. Along with this shift of commercial policy, its international political stance continued as one of more genuine nonalinement. Following the enactment of an investment code on April 4, 1962, providing incentives to industries considered of special importance to the development of Guinea, and signing of an Investment Guarantee Agreement with the United States on May 9, 1962, the Ministry of Economic Development was established in January 1963, to promote industrialization.

In 1961 Guinea expropriated the properties of the Aluminum Co. of Canada, Ltd., local subsidiary engaged in mining bauxite and opening up larger deposits. With the serious decline in the 1962 foreign trade, the country's economic situation became very acute; serious shortages of spare parts and vital commodities existed and developmental projects, programed in the 3-year plan, were far behind schedule, or, in some cases, not even started. Thus the new agreement for bauxite development negotiated in 1963, and the encouragement given iron and diamond mining became of considerable importance for the future, particularly in view of the slow decline in agricultural production. The opening of diamond fields to private exploitation was described as another step toward liberalization of the economy and was designed primarily to provide mining opportunities for individual Guinean initiative.

On June 30, 1963, Guinea's first 3-year plan officially came to an end. The budget of the plan called for a total investment of GFr45,154 million. Despite substantial foreign assistance (most of it from the Communist countries), several of the plan projects had miscarried, many remained incomplete, and some were abandoned. Progress was made in resolving the many difficulties between Guinea and France, and in May an agreement was reached to set up a mixed commission to adjudicate the claims of private French firms whose assets had been taken over by the Guinean Government and to secure hard currency transfers for firms whose Guinean franc earnings had been blocked. On September 28, Guinea became a member of the International Monetary Fund and the World Bank.

SOURCE MATERIAL

Information on the industry in 1963 is meager and comes mainly from the U.S. Embassy in Conakry. Production and export data are mainly estimates, and, in the case of diamonds, they are open to question. Production of diamonds undoubtedly was much greater than shown, and additional output is quite apparently reflected in the large exports from adjacent Liberia, a nonproducer. Background data are from the technical press and brochures of the principal mining companies.

Digitized by Google

PRODUCTION

The constantly growing increase for alumina is the most salient feature of production during the 1959–63 period. Bauxite output did not parallel this growth because of the significant local events adversely affecting the industry. The fluctuations in iron ore production have reflected world market conditions and the special characteristics of the ore rather than mine productive capability. The unreliability of the data available on diamonds handicaps any interpretation of their significance; however, regardless of absolute quantities the trend was probably downward.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963

[1] In addition, gold, cement, and various construction materials have been produced in some years but no quantitative data are available.
[2] Estimate.
[3] Exports.
[4] Sales on tender only. Some additional stones were probably sold abroad by the Guinean Government and much local production is believed to have been diverted to Liberia. Moreover, some of the stones sold by tender were stones originating in adjoining countries, other than Liberia.

TRADE

Data available on quantities of metals and minerals traded by Guinea are limited to the major export items. In 1962 the unofficial total valuation of the major import items was GFr2,622 million, 16 percent of all imports (GFr2,134 million and 12 percent in 1961). The 1962 imports reportedly consisted of metals, GFr887 million; cement, GFr420 million; fertilizers, GFr127 million; and petroleum refinery products, GFr1,188 million. The corresponding 1962 value for exports totaled GFr8,352 million (GFr10,062 million in 1961), comprising about two-thirds of all exports in both years. Alumina exports were valued at GFr7,000 million in 1962, followed by those of iron ore (GFr833 million), diamonds (GFr497 million), and bauxite (GFr22 million).

Available data do not indicate source of the imports of metals and minerals. The contribution of the European Economic Community countries is reflected in their exports to Guinea, totaling GFr492 million in 1962, and 10 percent of all Common Market exports to that country. The Communist countries apparently were major suppliers, and metals and minerals undoubtedly constituted an important part of Guinea's total 1962 imports from these countries, valued at GFr5,754 million (36 percent of imports from all sources). All imports from Morocco, Netherlands Antilles, Venezuela, and the United Arab Republic amounted to GFr927 million and probably would reflect a

Digitized by Google

part of the imports of petroleum refinery products. Exports from the Common Market included petroleum products valued at GFr118 million. Some petroleum imports also came from the Communist countries, and a part of the total imports from the United States valued at GFr1,814 million were petroleum products. Estimates indicate that France was the leading recipient of 1962 exports of metals and minerals, with 22 percent of the total, followed by Cameroon (18 percent), Norway (16 percent), and the United States (14 percent). Those to the United States (alumina and diamonds) comprised 94 percent of all exports to that destination. In 1962, in an attempt to hold down her growing indebtedness to Communist countries, Guinea increased shipment of iron ore to those areas and began to divert a part of her alumina production there.

TABLE 2.—Major exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1961	1962	Principal destinations, 1962
Metals:			
Aluminum:			
Alumina	462,901	457,653	France 118,215; Cameroon 99,780; Norway 88,537; United States 71,641.
Bauxite	378,412	[2] 44,389	Czechoslovakia 18,396; Hungary 10,334; Poland 493.
Iron ore	534,936	719,495	Poland 450,864; United Kingdom 118,400; West Germany 79,950.
Nonmetals: Diamond—carats	[3] 1,220,000	[4] 350,000	Belgium-Luxembourg 180,242; Switzerland 73,930; Israel 54,228.

COMMODITY REVIEW

METALS

Aluminum—*Bauxite.*—The greater part of the 1963 bauxite production was by Compagnie Internationale pour la Production de l'Alumine (FRIA), to meet the demands of its plant, approximately 1.4 million metric tons. This output came from the company's opencut mines situated in the immediate vicinity of the plant. The proven reserve of bauxite in the area was reported to be 140 million metric tons. The bauxite contains about 42 percent alumina; the silica content is remarkably low, but the iron oxide content is comparatively high.

The small remainder of the production came from the island of Kassa, one of the Los group, off the coast from Conakry, where a Polish-Hungarian force attempted to operate the mines formerly exploited by Société des Bauxites du Midi (BAMIDI), a fully owned subsidiary of Aluminum, Ltd., of Canada (ALCAN), exporting to European Communist countries as in 1962. Opened up since 1952, the Kassa mines exported washed and dried bauxite containing about 50 percent alumina mainly to Canada and West Germany, and

Digitized by Google

annual shipments reached a maximum of 540,000 metric tons in 1960. Activities were suspended in August 1961, and the installations were taken over by the Government of Guinea, following BAMIDI's nationalization effective November 23, 1961. This resulted from the company's previous notification to the government that due to its inability to solve the problems of long-term finance, the Boké project could not be completed by July 1964, as provided for in the convention of May 17, 1958; an alternative proposal was rejected by the government, and subsequently all company assets were expropriated without compensation.

BAMIDI's project, expected to include eventually United States and European aluminum producers, called for the exploitation of the bauxite deposits at Boké, 350 kilometers northwest of Conakry, with the annual production of 1.5 million metric tons of bauxite and 220,000 tons of aluminum. The reserves of the Boké area have been estimated to total 700 million metric tons containing 55 percent alumina. BAMIDI's investment was reported at the dollar equivalent of about GFr4,940 million, and completion of the project as planned would have required about GFr32 billion more.[3]

After 15 months of negotiations, the Government of Guinea signed a 75-year agreement on October 1, 1963, with the U.S. firm of Harvey Aluminum which set up a joint company, Compagnie des Bauxites de Guinea (CBG), to exploit the Boké deposits. Under the terms of the accord, Harvey and the Government of Guinea will share jointly in the profits according to a formula which was worked out during the negotiations. Total projected investment by all parties has been set at GFr12.35 billion. The first stage of development includes a planned annual production of about 1 million metric tons of bauxite and the construction of a chemical ore processing plant with an annual capacity of 10,000 tons. The next stage envisages the preparation of studies regarding an alumina refinery and an aluminum smelter, to be submitted within 3 years. Auxiliary projects, including the construction of a 137-kilometer railway, new roads, housing, and a port for shipping products, will be undertaken by the Government of Guinea and leased to the American firm. Guinea purchased a 15,000-ton ore carrier from the United Kingdom and will provide ocean transport for a substantial portion of the Boké production. The Kassa deposits are not a part of the Harvey agreement. As part of this agreement, CBG reserves the right to supply other countries or companies with bauxite, and so long as this is done, no further concessions will be granted within the Boké area.[4]

Alumina.—In 1963, FRIA reached the full capacity of its Kimbo alumina plant at Fria, 150 kilometers by rail north of Conakry, with a 5-percent increase over 1962. The company, capitalized at GFr8.4 billion, continued to be managed by the French partners, Pechiney-Ugine, holders of 26.5 percent of the stock, for the other members of the consortium consisting of the U.S. firm of Olin Mathieson Chemical Corp. (48.5 percent); British Aluminium Co., Ltd. (10 percent); Aluminum Industrie A.G. of Swiss domicile (10 percent); and the Vereinigte Aluminium-Werke, A.G. of West Germany (5 percent).

Digitized by Google

Total investment, nearly one-half of it in infrastructure, was reported in late 1963 as the equivalent of GFr37 billion. No progress was reported on original plans for the extension of annual plant capacity to 1,440,000 metric tons, nor on plans for the eventual production of aluminum; alumina output was entirely for conversion to metal, mainly at the stockholders' oversea plants.

Exports through June were 244,370 metric tons, and they reportedly continued to account for more than 50 percent of Guinea's exports to hard currency areas. By the end of 1963, FRIA had made considerable progress in the replacement of expatriate administrators and technicians by indigenous personnel, made possible through a successful training program inaugurated nearly 2 years before the alumina plant came on stream in mid–1960. The company has spent approximately GFr124 million a year since that time in developing skilled Guinean personnel for its operations.[5]

Iron Ore.—Compagnie Minière de Conakry, founded in 1947 by a combination of British and French interests, continued the production of lateritic iron ore from its mines on the Kaloum Peninsula, which is linked with the port of Conakry by a 12-kilometer railway. However, competition from other producing countries and the prejudice of some blast furnace operators against the comparatively low iron content (about 51.5 percent average) and high chromium content (about 1.25 percent average) again held down exports to far below the 1957 peak of 1,019,000 metric tons. Mined by opencut, the brown ore deposits are estimated to contain reserves of about 200 million tons of ore exceeding 50 percent iron content; production began in 1953, and although the installation has an annual productive capacity of 1,200,000 tons of marketable ore per year, this has never been achieved. Poland continued to be the principal recipient of the ore (245,714 tons), followed by United Kingdom (86,430 tons), East Germany (21,120 tons), Czechoslovakia (14,597 tons), and United Arab Republic (2,000 tons). In an endeavor to develop a technique which would overcome the high chrome content, the Austrian firm of Vereinigte Oesterreichische Eisen- und Stahlwerke, A.G. continued investigations and at year's end expectations were that these would prove successful and result in increased exports.

Some progress was reported toward the possible development of the iron ore deposits in the Nimba and Simandou mountains in southern Guinea, near the Liberian border north of the new mine of Liberian American Swedish Mining Co. (LAMCO) where production began in 1963. The project was being undertaken by an international consortium, the CONSAFRIQUE Group, originally established by a Swiss banking group and associated with European and American steelmakers (U.S. Steel and Jones & Laughlin). Japanese participation of 10 leading steelmakers, investing a total equivalent to GFr247 million, was announced in early 1963. Reserves for Nimba were reported at 250 million metric tons and for Simandou, 700–1,000 million tons. During the year the group sent in several small groups of engineers and steel company officers to study the problems attending the exploitation of the deposits. A larger team was scheduled to

[5] Hovey, J. A., Jr. Industrial Africanization: A Case History. Africa Report (Washington), v. 8, No. 12, December 1963, pp. 12–14.

Digitized by Google

arrive in the fall to prepare for the inauguration of surveys for roads, housing, and the railroad through the rough terrain to join the 266-kilometer LAMCO railroad in Liberia, about 50 kilometers away and connecting with Port Buchanan. Expectations were that ore might be moved out by 1967 or 1968, though world market conditions at that time will determine just when and in what quantities.

NONMETALS

Cement.—Limestone and clay suitable for the production of cement were discovered in an area about 45 kilometers west of Siguiri near the Mali border. Announcement was made of plans to utilize these raw materials in a plant to produce 100,000 tons per year, to supply most demands of Upper Guinea and the Forest Region. Reportedly the small plant built by the U.S.S.R. during the construction of a jet runway at the Conakry airport continued in operation; annual output was believed to be small.

Diamond.—Diamond production, in the hands of the Soviets since the 1960 nationalization of the two French companies working the Kerouane field, apparently fell to a new low, as reflected in the limited 1963 sales reported. Unconfirmed reports indicated that the Soviets found several new kimberlite pipes in the Kerouane area. In August several Western companies were making concerted efforts to form mixed companies (private and Guinean Government participation) to exploit either the old or the new fields; however, no announcement has been made of results. In a decree dated October 14, the government declared that deposits of alluvial diamonds, estimated by the Minister of Economic Development to contain about 200,000 carats, would be opened for private exploitation in an area bounded on the north and south by the parallels passing through Mazano and Sommansenia, respectively, on the east by the meridian of Femarodou, and on the west by the right bank of the Baule River. Diamond mined in this sector will be sold exclusively to the National Diamond Bourse, and operations are to be suspended for the period of May to July 31, corresponding to the farming season.

The Mineral Industry of the Ivory Coast

By Thomas G. Murdock [1]

THE IVORY COAST is one of the richest and most modern countries of French-speaking West Africa; however, its economy has continued to be essentially agricultural and its contribution to world mineral supply has been of little significance. Although other minerals are known, recorded production during recent years has been limited to small quantities of manganese ore and diamond and a few hundred kilograms of columbium-tantalum minerals. The only significant events in the mineral industry in 1963 were the establishment of a record high in manganese production and the beginning of construction of a refinery to treat imported crude petroleum.

In 1962 the country's gross national product (GNP) was US$624 million (CFAF154 billion).[2] In that year the value of the mineral production, estimated on the basis of unit value of exports as indicated by official foreign trade statistics, was CFAF965 million, exclusive of building materials, and only 0.6 percent of the GNP. The comparable value of production declined to CFAF848 million in 1963; consequently, the contribution to the GNP decreased.

Data on employment by the mining industry are not available; the labor force engaged in nonagricultural activities comprised approximately 70,000 of the 3.5 million inhabitants. Mine workers probably did not exceed 2,000 following the prohibition of diamond mining by individuals.

U.S. participation in the industry consisted of an affiliate of a New York diamond concern, which engaged in prospecting for diamonds, and of several oil companies, which held shares in the Ivory Coast petroleum refinery being constructed.

Mineral exploration was continued on an appreciable scale, and by yearend indications were that gold, manganese, diamonds, and lithium had primary potentialities for development. Beryllium, chromium, cobalt, rare earths, titanium, tin, and graphite were thought to have secondary potentialities. Copper, nickel, and platinum, although known to occur, did not appear to have much promise because of small deposits and lack of transportation facilities.

GOVERNMENT POLICIES AND PROGRAMS

No specific new mining legislation was reported for 1963. The Ivory Coast continued to encourage foreign investment and to indicate

[1] Mining engineer, Division of International Activities.

[2] African Financial Community (CFA) francs are used in the Ivory Coast. The exchange rate is US$1=CFAF246.8 (CFAF1=US$0.004052).

Digitized by Google

that it wishes to receive foreign capital from all Western countries, especially from the United States. Important steps taken by the Ivory Coast Government in this regard have included the enactment of a liberal investment code and the conclusion of an Investment Guaranty Agreement with the United States in 1961. The investment code has made it possible for companies undertaking investments of particular importance to the development of the country to be given priority status. Enterprises which are granted priority status benefit from measures for fiscal exemption or relief. The Official Journal of January 24, 1963, published Law 62/460 guaranteeing the Compagnie Mokta el Hadid, the French company engaged in manganese mining, that taxes would not be increased while it continues operations, to a maximum of 18 years.

During 1963 the government operated along the lines of a development plan originally intended to cover the period 1960–70 and altered to cover the period 1963–70. The plan has undergone constant revision. As part of its efforts to develop every sector of the country's economy, the government continued to explore the mineral resources of the country through a national corporation established for this purpose, Société d'État pour le Développement Minier (SODEMI). In 1963 this organization followed the program of geological exploration and minerals development for 1962–64 prepared by the Development and Resources Corporation of New York.

SOURCE MATERIAL

Background data are from a 1963 publication of the U.S. Government.[3] Data on production and some information on developments are from the dispatches of the U.S. Embassy at Abidjan. Most of the Commodity Review section has been abstracted from an article in the French press.[4] Foreign trade data are from official French and Ivory Coast publications. These sources report values for diamond exports at roughly one-third those shown by other official sources; however, the former are believed to be more reliable.

PRODUCTION

Manganese ore production in the Ivory Coast during recent years has been characterized by annual fluctuations; production for 1963 achieved a record high. Columbium-tantalum production more than tripled between 1959 and 1961 and then declined to below the 1959 level in 1963. Diamond output rose sharply to an alltime peak in 1961 because of large-scale uncontrolled mining by individuals; upon the suspension of this activity in 1963, output dropped below the 1959 level. Data were not available on the production of building materials; import statistics indicated that except for cement, dolomite, and lime, most requirements were met by domestic production.

[1] In addition, building materials were produced, but no quantitative data are available.

TRADE

In 1962 the total value of metal and mineral imports was CFAF4,443 million; they consisted of metals, CFAF1,413 million; nonmetals, CFAF1,012 million; and mineral fuels, CFAF2,018 million. The 1962 exports were worth CFAF1,211 million. Diamonds valued at CFAF555 million [5] and manganese ore valued at CFAF548 million accounted for most of the exports; the remainder was essentially scrap metals and reexported petroleum refinery products. In 1962, metals and minerals comprised 12 percent of all imports on the basis of value; however, exports of these commodities were only 3 percent of all exports.

France continued to be the leading supplier of metals and minerals, with 59 percent of the total; the European Common Market, of which the Ivory Coast is an associate member, supplied 70 percent in the aggregate. Venezuela, the main supplier of petroleum refinery products, accounted for most of the remainder, with 21 percent. Imports from the United States valued at CFAF17,941, were insignificant, and consisted mainly of petroleum refinery products. Although there was a comparatively small volume of metals and mineral exports, they were made to 21 countries. West Germany ranked first as a recipient with 37 percent, followed by France (27 percent) and the United States (9 percent). The European Common Market countries as a whole received 72 percent. Metals and minerals comprised 1 percent of all imports from the United States and 2 percent of all exports to that country.

On the basis of the value of all imports through November and assuming that metals and minerals again accounted for 12 percent, the value for these commodities for 1963 was CFAF4,872 million. Preliminary data indicate that exports of diamonds and manganese ore had respective approximate values of CFAF315 million [6] and CFAF478 million in 1963.

[5] Value indicated by official foreign trade statistics. The monthly bulletin of the Ivory Coast Chamber of Commerce and other sources place this at CFAF1,712 million; the reason for the disagreement is not known.

[6] Estimated value based on 9-month French Government data. Alternative sources place the value at CFAF932 million.

COMMODITY REVIEW

METALS

Columbium-Tantalum.—The small production of columbium-tantalite was again by a single operator, Société Anonyme de Recherches et d'Exploitations Minières de Côte d'Ivoire (SAREMCI), from the deposit 3 kilometers west of Bouake. The ore is recovered from quartz gravel which is mined as a building material. Exploration at depth has indicated that the deposit is strictly alluvial. The Société d'Etat pour le Developpement Minier (SODEMI) began exploration for the pentoxide minerals in the Issia region and discovered several small tantalite placers which can be worked by individual small-scale miners.

Gold.—The French Bureau de Recherches Géologiques et Minières continued exploration of the gold deposits at Ity, between Toulepleu and Danané, where work started in 1958; excellent results were reported. Following a discovery on Mont Flotouo, where gold had been found in the superficial lateritic clay, exploration indicated about 5 tons of gold in ore averaging 0.32 ounce per ton. In 1963 this occurrence was explored at depth; a mineralized formation 8 meters wide, 40 meters long, and 65 meters deep with an average gold content of 1.18 ounces per ton was found. At yearend work was continuing at this deposit to evaluate the mineralization within the zone of alteration where opencut mining would be possible. SODEMI began exploration work in the Lobo basin, between Issia and Soubré, and by yearend two areas containing an aggregate of several tons of gold had been proved.

Manganese.—The 1963 production consisted of 109,222 metric tons of lump ore containing 46 percent manganese and 29,841 tons of fines with 38 percent. The entire output came from the mines of Compagnie Mokta el Hadid in the Grand Lahou region; the increased production was attributed to the inauguration of a washing plant. Exports in 1963 were 104,843 metric tons, all of lump material and mostly to European Common Market countries. Exploration of manganese occurrences continued; the Mokta company prospected an area southwest of the producing mines, and a reserve of 80,000 tons of 45 percent ore were reported. In 1962, Direction de la Geologie et de la Prospection Minière (DGPM) had investigated the Ziemougoula deposit north of Odienne and the manganiferous outcrops east of Toumodi. In 1963 SODEMI was engaged in preparation of an economic study of the DGPM findings. The Grand Lahou manganese is transported from the mines to Abidjan through the net of coastal lagoons. In 1963 work was underway to improve transportation through the lagoons.

Titanium.—SAREMCI continued laboratory investigations of the ilmenite-bearing beach sands from Grand Lahou and Addah. Studies of beneficiation equipment for these sands were carried out in France in preparation for the early installation of a pilot plant. Estimates place the ilmenite reserve at 500,000 metric tons with a titanium content above 50 percent; the sands also contain small quantities of rutile and zircon.

Digitized by Google

NONMETALS

Building Materials.—SODEMI continued a search for building materials and discovered a large deposit of brick clay in Basse Comoé, near Grand Bassam, and extensive gravel deposits less than 30 kilometers from Abidjan. This company also investigated deposits of clay for ceramic use and glass sand.

Diamond.—The 37-percent decline in diamond production was largely due to the successful military closure of the Séquéla region to the wasteful mining by individual African diggers. In 1962 these diggers sold about 100,000 carats to the buying offices, accounting for 35 percent of the production. In 1963 the buying offices bought only 2,100 carats of production by individuals. The remainder of the production came from the three companies that also were active in 1962.

SAREMCI produced 155,614 carats (169,239 in 1962) from its Tortiya deposit. The slight decrease was due to declining richness of the deposit, which has been worked since 1948. The company installations include modern mining equipment and a treatment plant designed to work satisfactorily on low-grade feed. Exploration was continued, and deposits containing 110,000 carats were found. The 1964 production target was announced at 160,000 carats, treating gravel which would be still lower in grade than that of 1963.

Société Diamantifère de Côte d'Ivoire produced 21,275 carats (11,386 in 1962) from its mines about 30 kilometers north of Séguéla and continued a program of improvement of mining and treatment equipment. Expectations were 40,000 carats could be produced in 1964.

Société Minière des Bandamas, an affiliate of SAREMCI created in 1961 to exploit the deposits discovered within the old general permit of SAREMCI, produced only 670 carats (3,286 in 1962). This small recovery was the result of experimentation on the treatment of gravels coming from different deposits. Prospecting continued along the Maraboué River south of the Séquéla-Bouaké road, and deposits in the present bed of the river and in adjacent terraces were discovered. The first unit of a washing plant was to be installed in 1964.

Société Waston, an affiliate of Diamond Distributors, Inc., of New York and founded on March 6, 1963, carried out an exploration program within the Séquéla diamond area, under the agreement of association with SODEMI. At yearend alluvial reserves had been discovered and mining operations were being planned. Exploration of kimberlite pipe deposits reportedly had given encouraging results.

The Diamond Corporation Côte d'Ivoire, Limited, an affiliate of the South African De Beers Interests, continued prospecting, both for its own interest and for that of Société Israel Corporation Diamond, in the central and southwestern parts of the country, areas granted the firms in 1962. Diamond indications were found in the Maradiassa region in the central area, and detailed exploration was scheduled for 1964.

The 1963 exports were 213,507 carats, of which 186,182 came from the output of the companies. The remaining 27,325 carats was exports by the Ivory Coast Government purchasing offices, which bought diamonds brought from other African countries that apparently were

Digitized by Google

not listed as Ivory Coast imports. Exports in excess of production came from existing stocks.

MINERAL FUELS

Petroleum.—The French-controlled Société Africaine des Pétroles continued to hold its partly offshore 5,784-square-kilometer permit, where unsuccessful drilling was carried out in 1960 and 1962. Subsequent activity consisted of seismic work complementing earlier investigations, and at yearend an interpretation of results was underway. Expectations were that this would be completed by April 1964, and two wells were to be put down if the results of the seismic work were favorable.

Work began on the construction of the 700,000-metric-ton-per-year Abidjan refinery of Société Ivorienne de Raffinage (SIR); this installation was scheduled for completion in 1965 and will cost CFAF3,000 million. SIR was formally established in October 1962; its stockholders comprise Bureau de Recherche Pétroliere (25 percent), Ivory Coast Government (10 percent), Socony Mobil Oil Co. (18.2 percent), Shell Oil (14.7 percent), Compagnie Français de Pétrole (13 percent), British Petroleum Co., Ltd. (10.2 percent), Texaco Inc. (7.9 percent), and Esso (1 percent).

During the year, Société Générale Italienne des Pétroles completed their storage facilities in the Vridi industrial area of Abidjan and retail outlets in and around that city, following the granting of their operating authority by the Ministry of Finance, Economic Affairs and Planning in May.

The Mineral Industries of Kenya, Tanganyika and Uganda

By Thomas C. Denton [1]

THE CONTIGUOUS former British territories of Kenya, Tanganyika, and Uganda in East Africa have become fully independent countries within the British Commonwealth of Nations. This status was officially established on, respectively, December 12, 1963, December 9, 1961, and October 9, 1962. Investment guarantees through the U.S. Agency for International Development of the Department of State were available to U.S. citizens and corporations for Kenya and Tanganyika by July 15, 1964. For each of these countries guarantees were available with respect to convertibility, expropriation, and war risk, including guarantees against loss due to revolution and insurrection; also extended risk.

As a group the new countries were known as British East Africa (BEA). Such facilities as railways and harbors, collection of customs and excise revenue, postal and telecommunications services and civil aviation were operated for BEA as a whole. As of December 31, 1963, the scheme was being continued. The services as a whole are known as the East African Common Services Organization for which the top Authority consists of the Heads of the three East African Governments. The agency for collection of customs and excise revenue is known as the East African Customs and Excise Department, which also issues annual trade reports for the three countries. In addition, the countries have established a common market known as the East African Common Market (EACM), within which freedom of trade is insured by tripartite agreements providing for interterritorial movement of commodities under a system of consignor declarations. Nevertheless, the great bulk of the trade of the three countries still is with countries outside the EACM. With respect to metals and minerals, the net exports of Kenya within the market in 1962 comprised principally iron and steel semimanufactures, cement, gypsum, lime, and salt. Imports were negligible. Tanganyikan exports were negligible. The principal import was cement from Kenya. The largest export of Uganda is electric power generated at Owen Falls, which is transmitted both to Kenya and Tanganyika.

Before independence the currency of the new countries was a decimal currency the standard unit of which was the East African shilling, controlled by the East African Currency Board, which maintained a stable rate of sterling exchange. As of December 31, 1963, this was

[1] Africa specialist, Division of International Activities.

Digitized by Google

still the situation with respect to the currency of each of the three countries. One East Africa Shilling (EAsh) equals US$0.14, and 20 EAsh are equivalent to 1 pound sterling or US$2.80.[2] Pounds sterling are used in the chapter.

KENYA

The major event in the mineral field was the beginning of petroleum refining at Mombasa late in the year. No important changes occurred either in the pattern or value of production of other commodities. As for many years past, cement and soda ash contributed the great bulk of value—about 76 percent in 1963. Exclusive of construction materials and materials of cement manufacture, some 15 additional minerals were produced.

While not a significant supplier to world mineral markets Kenya mineral industry is important in the domestic economy. Its contribution to gross national product (GNP) in 1962 was about 1.9 percent, mineral production that year having been valued at £5.1 million (approximately US$14.3 million) and GNP estimated at US$735 million.[3]

The total persons employed in 1962 was 1,566 of whom 1,394 were Africans, 90 Asians, and 82 European (Whites). Expenditures in 1962 totaled £1,370,947—66.2 percent went into prospecting and 33.4 percent into mining and milling; the remaining 0.4 percent went into development. Basic cash wages paid were £160,354 to Europeans, £154,189 to Africans, and £66,086 to Asians. There were 258 registered holders of prospecting and/or mining titles at the beginning of 1963.

GOVERNMENT POLICIES AND PROGRAMS

The stated policy of the Kenya Government toward mining is to encourage the industry. Royalties are levied at low rates and mining machinery enters the country free. In addition the Mines and Geological Department in Nairobi maintains assaying and mineral dressing laboratories. Minerals are identified; Geiger counters are rented to prospectors; advice on geology, prospecting, and mining is furnished; and elementary prospecting courses are conducted twice a year.

In mid-December 1963 the government took action that weakened seriously the outlook for the important soda ash and cement industries of Kenya. A trade embargo was placed on South Africa, which has been the principal customer for soda ash and the supplier of anthracite for the cement industry. The Kenya Government at once began strenuous efforts to offset its elimination of the South African market by seeking to expand other markets and to find new outlets. Solution of the anthracite problem has been difficult because alternative cheap sources are not available.

SOURCE MATERIAL

The principal sources of information on Kenya were professional trade journals (Annual Review issue of Mining Journal (London),

[2] Union-Castle Mail Steamship Company, Ltd., Yearbook and Guide to East Africa. 1964. U.S. Embassy Dispatch Kampala A–325, Mar. 28, 1964.

particularly), reports of the Mines and Geological Department of Kenya, reports of other departments of the Kenya Government, and U.S. Bureau of Mines Mineral Production Questionnaires, returned from Kenya by the U.S. Foreign Service. Dispatches of U.S. Foreign Service posts in former British East Africa also were consulted.

PRODUCTION

During 1959–63 fluctuations in the value of Kenya mineral output were minor, value ranging between £5 million in 1963 and £5.4 million in 1961. Throughout the period the combined contribution of cement and soda ash was 76 percent or more, with cement generally providing about three-quarters of the total contribution. In 1963 the three next largest contributors were copper, salt, and gold in that order. If markets for soda ash large enough to replace that of South Africa are not found, a substantial drop in the value of Kenya mineral production appears probable.

[1] Includes oxides of rare earths.
[2] Provisional.
[3] Cement materials were reported for 1963 as follows: Limestone, 495,587 metric tons; clays, 73,680; volcanic ash, 845; gypsum, 20,729. For 1961 and 1962 no distinction was made between gypsum used for cement and for noncement.
[4] In 1963 semiprecious and ornamental stones were reported as follows: Augite, 113 kilograms; rose quartz, 21 tons; corundum and apatite, 4 kilograms; zoizite, 714 kilograms.

TRADE

Compared with 1961, mineral exports in 1962 fell by 14.8 percent to £2.3 million. The drop largely resulted from a decline in soda ash exports of more than 22 percent to £1.2 million. In 1962 more than 41

Digitized by Google

percent of soda ash exports went to South Africa, with India and Pakistan the next largest customers. It is noteworthy that in 1962 exports of 4,070 metric tons of copper concentrates valued at £480,796 went to Japan. Earlier the concentrates generally had gone to the smelter at Jinja, Uganda, to which the haul is short and mostly by water.

In 1962 mineral and metal imports, including metal semimanufactures, totaled £14.7—approximately 21 percent of the value of all imports from outside the East African market. Refined petroleum products accounted for about 54 percent of the total and iron and steel semimanufactures nearly 36 percent. Imports of mineral fertilizers were more than £1 million.

TABLE 2.—Kenya: Exports of metals and minerals, to countries outside the East Africa Common Market

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Copper, concentrate	3,726	4,070	All to Japan.
Gold, troy ounces	12,100	8,917	West Germany 8,371; United Kingdom 546.
Silver, do	37,836	46,303	West Germany 46,158; United Kingdom 146.
Nonmetals:			
Asbestos	32	18	All to Denmark.
Cement	95,114	105,548	Mauritius 43,482; Aden 24,046; Reunion 10,086; Somalia 7,698; Bahrain 5,691.
Diatomite	1,204	1,230	United Kingdom 990; South Africa 180.
Gem stones, other than diamond, £ sterling	1,115	--------	
Graphite	143	82	India 41; United Kingdom, 41.
Gravel and crushed stone, £ sterling	663	495	Zanzibar 480.
Lime	(1)	27	Zanzibar 25.
Mica, kilograms	--------	227	All to United Kingdom.
Minerals, crude, not elsewhere classified, £ sterling	1,232	1,183	Ships' stores 1,168.
Salt	765	692	Congo 678.
Sand, £ sterling	280	18	All to ships' stores.
Soda ash, sodium carbonate	144,962	112,987	South Africa 46,542; India 18,968; Pakistan 11,768; New Zealand 5,899; Siam 5,574; Singapore 4,826.

COMMODITY REVIEW

METALS

Copper.—Copper was produced in the Macalder Nyanza mines, a short distance inland from Lake Victoria. The report for 1962 of the Mines and Geological Department of Kenya stated that no new sources of copper were developed that year. Available information indicated the same situation for 1963.

Gold and Silver.—In 1963 output of both gold and silver improved slightly from 1962. The combined value was £137,000. Most of the gold and silver was a byproduct from copper ores of the Macalder mine. In 1962 Macalder provided 94 percent of gold output and nearly 100 percent of silver. There were seven other contributors.

NONMETALS

Cement.—Two plants accounted for the cement output: One is near Mombasa and uses coral, limestone, and clay quarried locally; the other is near Nairobi and uses crystalline limestone from Sultan Hamad.

Digitized by Google

Both plants must import coal which South Africa used to supply. The combined output of the plants in 1963 was valued at £2.5 million. Local raw materials consumed included 495,869 metric tons of Kun Kar limestone, 73,679 tons of clay, 845 tons of volcanic ash, and 21,144 tons of gypsum.

Soda Ash.—Magadi Soda Co., a subsidiary of Imperial Chemical Industries, Ltd., of Great Britain, is the source of an important output of soda ash. The company exploits an unusual deposit situated about 118 kilometers southwest of Nairobi at about 610 meters above sea level, where temperatures rarely are lower than 70° F, and 100° F is not unusual. The deposit consists of trona ($Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O \cdot$) fairly evenly distributed over about 60 square kilometers of Lake Magadi. The deposit is from 2.4 to 3.0 meters thick toward the center of the lake, where the trona rests on mud. The deposit is continually replenished by many surrounding springs from which great quantities of hot saline waters flow into the lake. It has been estimated that 65 million tons of solid trona exist on the lake, and that soda in solution amounts to 20 million tons.

The trona is collected by a dredge floating on the lake. Solid lumps of trona mixed with liquor are crushed on the dredge and pumped as a slurry through a floating pipeline to a beneficiation plant on shore. The plant turns out soda ash with a guaranteed minimum sodium carbonate content of 97 percent. Byproducts consist of salt for local consumption and minor quantities of other alkali products, including household soda (recrystallized sesquicarbonate of soda), bicarbonate of soda, and sodium fluoride.

Production of soda ash at Magadi began shortly before World War I and since has continued without interruption. By the end of the war output had reached 12,193 metric tons annually and 46,738 tons by 1922, the increase in the interim being largely based on sales to Japan. During 1959–63 annual output ranged from 103,506 tons (1963) to 153,487 tons (1959).

As indicated earlier, South Africa has been the major market for Magadi soda; it has also been a market for Magadi salt. The loss of the South African market probably will be permanent inasmuch as South Africa proposes to establish production at home on a scale at least large enough to meet domestic requirements.

MINERAL FUELS

Petroleum.—BP-Shell Petroleum Development Co. of Kenya, Ltd., continued its search for oil. The company had permission from the Kenya and Tanganyika Governments to explore for oil along the coastal strip from the Somalia border to southernmost Tanganyika, including the islands of Pemba and Mathia. In 10 years of work along the coastal area the company focused drilling at Walu and Pandangua. In January 1963, it was prepared to drill a hole at Walu for stratigraphic information to 14,000 feet if necessary.[4]

[4] U.S. Consulate General, Nairobi. Airgram 466. Jan. 14, 1963.

Digitized by Google

East African Oil Refineries, Ltd., at Mombasa began production from imported crude oil in November 1963. Performance to the end of the year was as follows: [5]

	U.S. barrels
Crude, processed	989,970
Liquefied petroleum gas	1,017
Premium gasoline	5,232
Regular gasoline	167,242
Kerosine	75,696
Gas oil	135,524
Diesel fuel oil	20,323
Heavy fuel oil	502,849

The company expects to process 2 million long tons of imported crude petroleum annually.[6]

TANGANYIKA

Diamonds provide about 70 percent of the value of mineral production and gold about 16 percent. The value of these and other minerals produced in 1962 was £7.5 million (US$21 million) and 3.5 percent of Tanganyika's estimated GNP of US$600 million. The volume of diamond produced was 2 percent of total African production and about 1.9 percent of world production, including an estimated 2.5 million carats for U.S.S.R. Gold output in 1962 amounted to about 0.4 percent of African production.

In 1962, the most recent year for which information is available, the average number of persons employed by mineral industry was 13,534. Of the 12,857 Africans recorded, about 25 percent were self-employed, either as members of the Mica Mining Cooperative Societies or in other small mining and prospecting groups. More than £3.5 million was paid in wages and salaries, of which nearly £1 million was African wages.

During 1963, developments bearing on the mining industry included prohibition of imports from South Africa, resulting in some hardship. Professional and technical personnel were not readily obtainable. Training schemes for Africans were operating, but some years will elapse before benefits begin to be felt.

Foreign technical and trade missions were active. Interest was shown in coal, iron, phosphates and base metal deposits. Limited transportation and communication facilities are a principal hindrance to development of known occurrences, and for some minerals local demand must first increase.

GOVERNMENT POLICIES AND PROGRAMS

During 1963 the position of three marginal gold mines remained weak. The government was considering a program to subsidize the mines so as to prevent closure.[7]

The Tanganyikan National Assembly enacted a bill providing certain statutory guarantees to foreign investors. The bill empowered

[7] Source cited in footnote 6, p. 191.

Digitized by Google

the Minister of Finance to grant certificates to foreign nationals who invest assets or reinvest profits in Tanganyika, providing he believes the investment will benefit the country. When approved status is granted, the investor is guaranteed the right to repatriate capital and profits and full compensation in the event of nationalization or expropriation of the relevant enterprise.[8]

The government established the Tanganyika Development Corp., to encourage investment and industry and to promote economic development generally. A similar corporation in Uganda has succeeded in these fields, including mining.

SOURCE MATERIAL

The principal source of information on Tanganyika was a review of the mining industry in 1963 issued early in 1964 by the Mines Division of the Ministry of Commerce and Industry. Other sources included other publications of the Tanganyikan Government, trade journals (particularly the Mining Journal (London)) and dispatches of the Foreign Service of the United States.

PRODUCTION

The value of mineral production in 1963 as measured by local sales and exports was £7.2 million, £300,000 lower than in 1962. The decline was mainly due to lower diamond output. Gold output was 4,490 ounces lower than in 1960, when peak production for the period 1959–63 occurred.

In 1960–62 local sales of minerals produced in Tanganyika were, respectively, £428,052, £459,362, and £390,847, mostly comprising construction materials and salt.

[1] Copper content of exports and local sales.
[2] Including gold in lead concentrates exported amounting to: 10,391 ounces in 1959; 8,963 ounces in 1960; and 521 ounces in 1961.
[3] Provisional.
[4] Includes corundum.
[5] Reported in cubic feet; conversion factors were: clay, 105 pounds per cubic foot; gravel, 100; sand, 90; stone, 100; and for 1961 and 1962 all 4 combined, 100.
[6] Data not available.
[7] Includes 42.2 kilograms crude ruby; 6.35, rough ruby and sapphire; 4.33, ruby bearing corundum ore. In addition, there were 1,079 kilograms of chrysoprase reported in 1961, and 363 kilograms of miscellaneous gem stones (including chrysoprase and zircon) reported in 1963.

TRADE

Provisional figures for the value of exports in 1961 and 1962 are, respectively, £7.5 million and £7.1 million,[9] the decline in 1962 being largely due to a decrease in diamond exports; likewise exports declined further in 1963, to £6.7 million.[10]

Following the usual pattern, exports of diamonds, gold, and silver in 1962 went to the United Kingdom, which thus received by far the largest share of mineral exports by value.

Mineral and metal imports in 1962 at £6.3 million were about 16 percent of the value of all imports. Refined petroleum products accounted for 59 percent of the total; iron and steel manufactures, 31 percent. Imports of cement from outside the East Africa Common Market were valued at £83,337. For more detailed information on imports see table 3.

COMMODITY REVIEW

METALS

Gold.—Rhodesia-Katanga Co., Ltd., which controls Geita Gold Mining Co., Ltd., decided to abandon the Geita mine because it had become difficult to operate profitably. Extraction of the remaining ore was expected to be complete by the end of 1965. Closure of the Geita, largest gold mine in Tanganyika, would be severely felt in the district. The government explored with the company possibilities of subsidizing the operation to extend the life of the mine.

At the Kiabakari mine, of Tangold Mining Co., Ltd., ore was being drawn from the 850-foot level. Development was concentrated between the 1,150-foot level and the 1,550-foot level. The future of the mine largely depends on the grade of the reserves between the levels. The company prospected outside its lease but by the end of the year had indicated that it would allow its exclusive prospecting licenses to expire.

At the Buhemba mine of Buhemba Mines, Ltd., nearly wholly owned by Williamson Diamonds, Ltd., underground work was concentrated in workings at the ends of the ore body, to maintain uniform tonnage and grade of ore going to the mill. Advice and loaned equipment from Williamson helped to improve workings and to overhaul the mill and powerplant. In time costs should be improved. Two

Digitized by Google

1,000-kilowatt generating sets had been received by the end of the year, and a new 75-horsepower hoist had been ordered. While mill recovery improved, total results for the year indicated a loss would be incurred. Plans were to mine the Hospital vein by open pit, to provide cheap ore near the mill.

In Lupa goldfield in Chunya District the last vein mine, Ntumbi Reefs, Ltd., was abandoned, and the leasers emigrated to South Africa. Working placers and buying gold is now nearly entirely in the hands of Africans, who have organized the Lupa Gold Mining Co-Operative Society, headquartered at Chunya.

In North Mara District the owners of the Mara mine also emigrated to South Africa, but a partner-leaser continued to produce successfully from small occurrences. Other companies attempted unsuccessfully to open small mines in the field. Failure in part was due to lack of understanding of the problems of the area, some of which illegal mining and gold buying complicate, due to the proximity of the Kenya border.

There was steady production of coarse alluvial gold in Nzego District, following opening of the Mpanda Closed Area to prospecting. Possibilities of establishing another cooperative society for African miners were being considered.

Tin.—Steady improvement in the price of tin during the year encouraged operators in the Karagwe tinfield, but there were local difficulties resulting from flooding of the Kagera River and from troubles in Rwanda. Tin smuggling across the border increased; it was clear that not all of the concentrate allegedly produced by small operators came from claims in Tanganyika. In addition, attempts were made to mine illegally on the lease held by Kyerwa Syndicate, Ltd. At the Kaborishoke mine of the Syndicate tonnage treated increased substantially, but sales of tin concentrate declined. It was necessary to remove low-grade material to reach richer ore below. The nearby Rwabashoga occurrence was leased to two contractors, which may discourage illegal miners in the area. No attempt was made to solve the problem of tailings disposal; compensation to local cultivators for crop damage continued. Small producers had disputes about prices and assays with the tin buyer at Kikagati; possibilities of establishing a cooperative export society were discussed but no action was taken.

NONMETALS

Cement.—Tanganyika Portland Cement Co., Ltd., began construction of a plant near Dar es Salaam and applied for a lease for limestone and clay.[11]

Diamond.—Williamson Diamonds, Ltd., the only diamond producer, is owned equally by the Tanganyika Government and De Beers Consolidated Mines, Ltd. (De Beers), the operator. Williamson has two mines, the principal Mwadui mine and adjacent Alamąsi mine of New Alamasi (1963), Ltd., which as of January 1, 1963, became a wholly owned subsidiary of Williamson.

The main treatment plant at Mwadui operated at capacity during 1963. Ground treated totaled 2,643,638 tons, and 185,088 tons was

[11] Source cited in footnote 6, p. 193.

Digitized by Google

handled by the prospect plant, of which 46,776 tons was from Alamąsi. Total recovery was 571,632 carats, equivalent to 20.55 carats per 100 tons. The corresponding figures for 1962 were 636,856 carats, equivalent to 22.77 carats per 100 tons. Summarized financial results for the year ended December 31, 1963, were as follows:

	Value in Rands [1]
Diamond account	R8,031,000
Sundry revenue	117,000
	8,148,000
Deduct: Mining and general expenses and sundry charges	3,955,000
Profit for the year	4,193,000
Deduct: Provision for taxation	916,000
Surplus brought forward and adjustments for previous year	3,277,000
	153,000
Total credit to appropriation account	3,430,000
Transfer to reserves R1,148,000; dividends R2,000,000	3,148,000
Profit unappropriated	282,000

[1] 1 Rand (Republic of South Africa) equals US$1.40.

At Mwadui mine the policy of working lower grade ground, together with heavy rainfall and difficulties with a new primary crusher resulted in treatment of a greater proportion of kimberlitic material than of clayey but rich superficial gravels. Some difficulty developed in attracting and retaining experienced technical personnel. Africans were being trained at company expense for posts in all departments but some time would elapse before they would be able to take over. Breakdowns leading to lost time and production occurred that were partly from lack of skilled supervision. Underground work in the kimberlite pipe itself was hampered by heavy inflow of water, and pumping station capacity had to be increased by 50 percent.

Acquisition of the Alamąsi Co. by Williamson made available to Alamąsi mine substantial financial, technical, and administrative facilities of the parent company. By the middle of 1963 Alamąsi was yielding an operating profit. The plant was running on three shifts with a smaller staff than previously; most were Africans. Labor relations were greatly improved.

During the year Williamson surrendered two-thirds of the lands over which it held exclusive prospecting rights; but elsewhere the company continued to prospect for kimberlite pipes. Possibilities for finding another large diamond mine thus have not been completely exhausted according to the Mines Division of Tanganyika.[12]

The Belgian diamond prospecting company known as INTERFOR ceased operations in Tanganyika on December 31, 1963. An extensive prospecting campaign in the Mara and Dodoma areas had disclosed nothing to warrant further expenditures.

[12] Tanganyika, Ministry of Commerce and Industry. A Review of the Mining Industry in 1963. Mines Division, mimeographed paper, 1963, p. 5.

Digitized by Google

During the year individuals were granted authority to prospect for diamonds outside areas reserved to Williamson, but little or no significant work was done.

Mica.—The Uluguru and Kikeo Mica Mining Co-Operative Societies hold mining leases in the Uluguru Mountains. Much of Tanganyika mica production in 1963 came from the operations. Most of the miners are also cultivators, so that as usual output fluctuated seasonally. Once during the year the miners clearly indicated that they wished to bypass the buying firms in Morogoro and to sell the mica directly overseas. Wiser counsels prevailed when they became aware of financial and other problems involved.

Salt.—During the year improvements to the Uvinza Salt Works by Nyanza Salt Mines, Ltd., resulted in brine being drawn from drill holes with a density higher than that of natural springs. Brine reservoirs were roofed so that the rainy season could no longer adversely affect production. Potential demand for salt in Central Africa is very large, and the Uvinza Salt Works can now meet any foreseeable increased demand, according to the Mines Division.

At Utondwe and Bagamoyo, H. J. Stanley and Sons, Ltd., were the largest producers of salt by solar evaporation of sea water. The company has pioneered mechanical methods of salt cropping in Tanganyika. The processes have not yet been perfected due to the corrosive conditions under which the machines work.

At most other coastal saltworks, production was normal, but at times was reduced by unseasonable rains. The recently completed Ruvu-Mnyusi rail link would help these other producers to cut transportation costs and improve inland distribution of salt, according to the Mines Division.

MINERAL FUELS

Coal.—A new inclined shaft at Ilima Colliery in the Rungwe district improved coal extraction. The market for Ilima coal was restricted to local tea estates.

Petroleum.—While BP-Shell Petroleum Co. of Tanganyika, Ltd., did no fieldwork during 1963, studies were made of previous geophysical and geological investigations for planning a field program to prove structures suitable for drilling in 1964.[13] The company renewed its exploration license but over an area reduced to 137,270 square kilometers compared with the large area originally held along the coastal belt.

Ente Nazionale Idrocarburi (ENI), controlled by the Italian Government, concluded an agreement with the Tanganyika Government for construction at Dar es Salaam of a petroleum refinery, having initial annual crude capacity of 600,000 tons. The company organized to own and operate the refinery was Tanganyikan Italian Petroleum Refining Co. (TIPER). ENI was to furnish the capital to build the refinery but the Tanganyikan Government was holding an option to acquire a 50 percent interest in it.[14]

UGANDA

Since 1958 the principal product by value of the small mineral industry has been blister copper, which reached a record peak in 1963. Besides cement, and rock quarried for road and other construction (about 95,000 tons in 1963), important quantities of beryl and small quantities of some 10 additional minerals and metals generally are also produced. Beryl resources are reported to be important;[15] this beryl and a large deposit of apatite and accessory pyrochlore appear to be the most significant mineral resources known in Uganda. The apatite is particularly important if export markets for the mineral are developed.

The value of Uganda mineral production in 1963 registered little change from 1962, respective values being £4.5 million[16] and £4.4 million. The value in 1962 was approximately 2.2 percent of the gross national product estimated for that year (US$475 million).[17]

In 1962 blister copper contributed more than 78 percent of the total value of mineral production and cement more than 14 percent. Mineral exports in 1962 at £3.8 million were about 9.7 percent of total domestic exports of £39.2 million, and 97 percent was copper. In 1961, the most recent year for which information is available, the average number of persons employed in mineral industry in Uganda was 5,546 Africans, 178 Asians, and 193 Europeans.

In 1961 Hunting Surveys, Ltd., of Great Britain, under contract to the Uganda Government, began an airborne geophysical survey of three regions in Uganda, totaling about 31,080 square kilometers, which was completed in 1963. Eighty-five percent of the cost of the survey was met by the U.N. Special Fund.

The agreement with the Special Fund provided that results of the survey would be published by the Uganda Government to insure maximum benefit to the economy of the country by making the results widely available. The first of several reports to be issued was published in December 1962.

The agreement also committed the Geological Survey of Uganda to a ground-followup program of work for at least 3 years, consisting of detailed ground geochemistry and geophysics. Results are available in Uganda for inspection. The followup in area C/D was completed in 1963 and was to be open to prospecting in 1964. Followup work elsewhere continued under the supervision of the Geological Survey.

GOVERNMENT POLICIES AND PROGRAMS

In 1963 the new Uganda Government encouraged foreign investors to participate and assist in the economic growth of the country. With that objective, Uganda offers several special tax and tariff concessions. The main government instrument to attract foreign investment is Uganda Development Corp., Ltd. (UDC). The Development Divi-

Digitized by Google

sion of UDC explores opportunities for new investments of all kinds and joins with private capital in new ventures. The largest foreign private investment in Uganda at yearend was in Kilembe Mines, Ltd. (copper), which UDC materially helped to establish.

Despite the favorable attitude of the government, relatively little new investment has occurred in Uganda since October 1962 when the country became independent. The reason frequently given was uncertainty resulting from the approaching independence of contiguous Kenya because Uganda is landlocked and most of its exports are through the Kenya port, Mombasa.

SOURCE MATERIAL

Source material on Uganda comprised mainly trade journals, reports of various departments of the Uganda Government, and dispatches of the U.S. Embassy at Kampala—particularly the airgrams. For commodity reviews the annual review for 1963 of the Mining Journal (London), was particularly useful. The annual review was the source of production figures for 1963.

PRODUCTION

During 1959–63 the value of Uganda mineral production, exclusive of rock quarried for road and other construction, ranged from £4.0 million in 1959 to the peak for the period of £4.5 million in 1963. Eleven minerals were produced in 1963 virtually unchanged in kind since 1959, except that no lead was produced after 1959 and no mica in 1963. Small-scale mining in the Kigezi district, suspended in 1954, was resumed on trial in 1961 and suspended again in 1962.

TRADE

Exports.—The value of mineral exports in 1961 and 1962 was, respectively, £3,215,256 and £3,810,510, contributing, respectively, 8.2 and 10.1 percent to total domestic exports of £39.2 and £37.6 million. In 1962 copper, which comprised nearly 95 percent of mineral exports, went principally to Spain (11,757 tons out of 15,799 tons exported). By November 1963, it was evident that exports to South Africa had sharply declined.

Imports.—Mineral imports in 1962 were valued at £3.4 million, nearly 13 percent of the value of all imports from outside the East African Common Market. Refined petroleum products and iron and steel semimanufactures accounted for, respectively, 65 percent and 17 percent of mineral imports. For greater detail on imports, see table 3. No figures were available to determine the effect of the Uganda ban on imports of South African products.

COMMODITY REVIEW

METALS

Beryl.—Production of beryl declined for the third year in succession because of low prices. Output in 1963 was less than 37 percent of that attained in 1961, when Uganda was the second largest beryl producer in the world after Brazil, contributing more than 9 percent of output.

Uganda beryl, containing about 11.5 percent BeO, comes principally from the Kigezi and Ankole Districts, from which total output during the 10-year period 1952–61 was 2,122 metric tons, of which Kigezi contributed 37 percent; Ankole, 63 percent.[18] Insofar as adequacy of resources are concerned, the future for beryl in Uganda appears good. The Annual Report of the Mines Department of Ugnada for 1961 stated in effect that production at the rate achieved in 1961 should be possible for some time.

[18] Mines Department, Uganda Protectorate. Annual Report. 1961, p. 3.

Digitized by Google

Columbium.—Tororo Industrial Chemicals & Fertilizers, Ltd., was expected to begin production of pyrochlore from apatite tailings late in 1964. The development is discussed under phosphate.

Copper.—Kilembe Mines, Ltd., financed largely in Canada, came into production in 1956, and has since accounted for virtually all Uganda copper production. At Kilembe the mine and concentrator are situated in a steep-walled valley in the foothills of the snow-capped Ruwenzori Mountains. The company generates its own hydroelectric power. Concentrates are conveyed by pipeline, largely by gravity, about 13 kilometers to Kasese, the railway terminus. From Kasese the concentrates are shipped by rail 435 kilometers to the company electric smelter at Jinga, power for which is supplied from the Owen Falls Station of the Uganda Electricity Board situated on the Victoria Nile a short distance downstream from Lake Victoria, the source of the Victoria Nile.

Kilembe was the sole copper producer in 1963. The company established a new record output, producing 16,216 metric tons of blister copper, having an estimated value of £3,630,256. From the mine, 1,004,170 tons of ore was sent to the mill, and a further 5,023 tons of ore from the oxide zone was sent directly to the smelter. The oxide opencut was exhausted during the year. Development totaled 16,297 meters. Development in the Bukangama section was mainly to prepare a large stope block and to explore on the 6,600-foot level. The 2,050 crosscut on the 4,500-foot level intersected ore. It was announced that an ore body containing at least 2.5 million tons had been discovered. The development insures continuation of the operation at least until 1973 or 1974.

Kilembe carried out considerable surface exploration in two areas. Results were negative.

Tin.—Production of tin ore increased to 233 long tons from 104 tons in 1962. Production was by small operators in Southwest Uganda, where vein and detrital tin deposits are widespread. In some areas water shortage hampers operations.

Tungsten.—Only one small hydraulic mine operated during the year. The government set up a commission to investigate measures to aid Ugandan tungsten miners, and a report was submitted.

NONMETALS

Cement.—Uganda Development Corp., Ltd., reported that the downward trend in cement sales caused by the building recession appeared to have halted in 1963. Any upward trend that might develop was not expected to be rapid. Production in 1963 by Uganda Cement Industry, Ltd., controlled by Uganda Development Corp. and the only cement manufacturer in Uganda, was 55,161 metric tons, compared with 81,621 tons in 1959.

Phosphates.—In the Sukulu Hills near Tororo in Eastern Uganda are large deposits of apatite with accessory pyrochlore. The deposits consist of apatite-pyrochlore-bearing soil, derived from underlying carbonatite. Reserves of the ore have been estimated at more than 200 million tons. The apatite is nearly pure theoretically and can be

Digitized by Google

concentrated into a product containing from 40 to 42 percent P_2O_5.[19] The deposits perhaps are the most important mineral resource presently known for Uganda. Interest in their possibilities dates back to 1945 or earlier.

Sukulu Mines, Ltd., and Tororo Industrial Chemicals & Fertilizers, Ltd., both subsidiaries of Uganda Development Corp., exploited the Sukulu deposits and manufactured superphosphate. Production of apatite concentrates and superphosphate in 1963 was, respectively, 7,072 metric tons and 7,288 tons, both figures representing substantial increase from 1962. It was expected that output would expand further in 1964. Planned annual production was to be 25,401 tons of superphosphate and 88,904 tons of soil, from which 14,123 tons of apatite would be produced. The sulfuric acid plant has a capacity of 10,669 tons per year. It was also expected that pyrochlore would be produced from apatite tailings in 1964.

Busumbu Mines, Ltd., continued to produce on a small scale. The ore was screened and shipped to Kenya for conversion to superphosphate.

MINERAL FUELS

Uganda lacks fuel resources other than wood, and the outlook for improvement of the deficiency in mineral fuels is not encouraging. All requirements therefore must be met by imports. However, the Owen Falls hydroelectric development on the Victoria Nile can supply more than sufficient electric power for present needs, and virgin water powers suitable for development exist elsewhere on the Nile.

The Mineral Industry of Liberia

By Thomas C. Denton [1]

THE outstanding event in the Liberian mineral industry in 1963 was the formal opening of the iron ore mine and harbor facilities of Liberian American-Swedish Minerals Co. on November 15. PresidentTubman officiated, and there were present Prince Bertil of Sweden and business and financial leaders from Sweden, West Germany, and the United States.

Iron ore mining has become the foundation of the domestic mineral economy and a significant contributor to world iron ore supply. Production has increased each year since 1957 and in 1963 reached over 6.5 million metric tons, about 2 percent of world output that year exclusive of production from Communist countries. Production ultimately may reach the order of 20 million tons annually insofar as adequacy of ore reserves is concerned. Besides the iron ore and substantial quantities of construction materials, additional mineral output in 1963 was limited to small quantities of diamonds and gold; however, exports of diamonds produced outside Liberia were large.

As a result of expansion in iron mining, in 1961 Liberian mining industry ranked first, ahead of rubber, in foreign exchange earnings. It ranked second after the rubber industry in employment; however, employment data are incomplete. In 1961, the most recent year for which complete trade statistics are available, iron ore exports of US$29.4 million [2] were nearly 50 percent of the value of all domestic exports and nearly 22 percent of the estimated gross national product of Liberia in 1962 (US$136 million). In 1963 the share of iron ore in the value of exports presumably was much larger inasmuch as the volume of ore exports increased nearly 125 percent over the volume in 1961. It is estimated that in 1963 around 20,000 unskilled laborers were employed by mines and by construction companies working on projects for mining companies.

West African Explosives and Chemicals Ltd. (EXCHEM) plans to manufacture explosives in Liberia early in 1964. EXCHEM will be the first company to produce explosives in West Africa. Its new type of explosive could reduce blasting costs significantly.[3]

Persistent rumors that iron ore exploration in the Putu range would be renewed were given fresh impetus when President Tubman announced the Government hoped to aid the project. Reportedly, an option was granted late in 1962 to Martin Hofer, a Swiss citizen who

obtained financial backing from the H. L. Hunt Co., which owns the Hunt Oil Co. (U.S.). The Putu area was explored to some extent by Liberian American-Swedish Minerals Co. (LAMCO) but was abandoned when LAMCO prospectors discovered the Nimba deposit.

In November 1963 the Free Port of Monrovia berthed the largest ship ever to call at the port. The motorship *Strassburg*, an ore carrier of 38,300 tons and 720 feet long, spent 3 days at the German-Liberian Mining Co. pier loading LMC ore for West Germany. It was announced that a US$200,000 dredging project would be undertaken to permit the port to handle even larger ore carriers.[4]

GOVERNMENT POLICIES AND PROGRAMS

The climate for investment in Liberia remained good. The Government has indicated that it intends to maintain its traditional open-door policy to foreign investment. At the same time the Government has made clear that it will press demands for additional training and employment of Liberians at all levels by foreign enterprises operating in Liberia.[5]

The Bureau of Natural Resources and Surveys includes the Mining Service, the Geological Survey, and the Cartographic Service. The following are some activities of these departments during the Liberian fiscal year ended August 31, 1963. The Chief of the Mining Service and his staff were mostly engaged in surveying mining claims and issuing various classes of licenses. Insufficient funds and staff prevented the Service from providing hundreds of gold and diamond miners the technical advice they needed. No drilling was done because funds were lacking for maintenance and replacement of equipment.

The Geological Survey was mainly engaged in mapping an area extending about 40 kilometers (25 miles) on either side of the Monrovia-Veinjama highway. The Survey also periodically checked the weightometers of Liberia Mining Co. and National Iron Ore Co.

Under the general agreement of October 6, 1955, a project agreement was executed between the Governments of Liberia and the United States for a Technical Assistance program under which modern topographic map coverage of Liberia will be undertaken; later geologic mapping will be done. The program includes on-the-job training of Liberians in the United States. The program will require 4 to 5 years to complete and will cost an estimated US$4.2 million, according to the Liberian Bureau of Natural Resources and Surveys.

SOURCE MATERIAL

Besides information gained by the author during visits, this chapter is mainly based on dispatches of the U.S. Embassy in Monrovia, articles in trade journals, and information supplied by official publications of the Government of Liberia, particularly the annual report of the Bureau of Natural Resources and Surveys for the year which ended August 31, 1963.

PRODUCTION

The outstanding aspect of Liberian mineral industry in recent years has been the steady increase in iron ore production. At the end of 1963 the boom seemed certain to continue for some years. Of significance also was the start in 1963 of mechanized diamond mining. Liberia's neighbors on all sides are important diamond producers, and it may be that Liberia will join their ranks in due course.

TABLE 1.—Metal and mineral production

[1] Estimate.
[2] Exports. Breakdown of total by quality estimated, except for 1963.
[3] Year ended Aug. 31, 1963.

TRADE

In 1960 and 1961, the value of exports of domestic merchandise was US$79.5 million and US$59.2 million, respectively. Exports of iron ore in 1960 of US$34.6 million contributed 44 percent of the total and nearly 50 percent at US$29.4 million in 1961. In 1960 diamond accounted for a further contribution by minerals of 3 percent, and in 1961, 4 percent. More recent data on diamond are not available, but information on company exports of iron ore is given under commodity review.

Imports in 1960 and 1961 were valued at US$69.2 million and US$90.7 million, respectively. Imports of metals, minerals, and mineral fuels in those years totaled, respectively, US$8.0 million and US$11.5 million, of which US$3.1 million comprised petroleum products. Imports in 1962 of iron and steel semimanufactures were US$5.5 million, and 65 percent of metal and mineral imports exclusive of petroleum products. The United States in 1961 was Liberia's major supplier of iron and steel semimanufactures and of petroleum products except gas-diesel oil of which Iraq furnished 59 percent.

COMMODITY REVIEW

METALS

Gold.—Up to August 31, 1963 no improvement in gold mining had occurred. A diamond rush occupied most gold prospectors and miners, who are familiar with hand placer mining methods applicable to primitive diamond mining in Liberia. Gold sales to the Bank of Monrovia amounted to 1,960 ounces. The figure is the only one available with respect to production, much of which goes to local goldsmiths and is not recorded.[6]

Iron Ore.—As indicated previously, iron ore production in Liberia in a few years may well be around 20 million tons of marketable product annually. In that event Liberia would rank about fifth after France among iron ore producers exclusive of Communist countries on the basis of relative country positions in 1963. At the end of 1963 three companies were producing ore and a fourth was preparing for production. All of the mines are open pit operations.

Liberia Mining Co., Ltd. (LMC).—The company operation is some 64 kilometers north of the Free Port of Monrovia to which it is connected by 3 foot 6 inch-gage railroad and through which the ore is exported. LMC, controlled by Republic Steel Corp., began shipments in 1951 and since has produced steadily and in generally rising volume. Exports in 1963 were as follows:

	Metric tons
Lump	1,203,420
Concentrates	1,139,795
Fines	251,787
Total	2,595,002

National Iron Ore Co., Ltd. (NIOC).—The company is owned 50 percent by the Liberian Government and 35 percent by Liberian citizens. The remaining 15 percent LMC controls.[7]

The NIOC mine is some 80 kilometers by rail easterly from LMC's mine. Concentrates comprise the great bulk of production. The first shipment was made in December 1961, through the port of Monrovia. Exports in 1963 totaled 2,105,207 metric tons. When fully equipped, the annual production capacity of the operation will be about 4 million tons of marketable ore.[8]

Liberian American-Swedish Minerals Co. (LAMCO).—The LAMCO iron ore concession at Nimba in the Nimba Mountains on the Guinea border is exploited jointly by LAMCO (75 percent) and Bethlehem Steel Corp. (25 percent), through the LAMCO Joint Venture Operating Co. LAMCO in turn is owned equally by the Liberian Government and Liberian Iron Ore, Ltd. (LIO), a Canadian holding company controlled by a Swedish syndicate in which are a group of Swedish companies. Under a special agreement, management of

Digitized by Google

LAMCO Joint Venture Operating Co. is in the hands of the Grangesburg Co. of Stockholm.[9]

LAMCO made its first commercial ore shipment in August of 1963 and by yearend had exported 1,797,445 tons. The targets for 1964 and 1965 are 7 million tons and 7.5 million tons, respectively. Reportedly, by 1970 exports could be stepped up to 12 million tons annually insofar as capacities of facilities involved are concerned.

The ore is shipped through the artificial port of Buchanan, to which the mine at Nimba is connected by 265 kilometers of U.S. standard gage (4 feet 8½ inches) railroad, the widest gage railroad in Africa south of the Sahara. (Gages elsewhere are 3 feet 6 inches and 1 meter.) Equipment and grades on the line are such that 9,000-ton-ore trains can be run to the port. At the port ships can load 45,000 tons of ore, and the harbor is being deepened to handle larger carriers.

The LAMCO project was carried out as a unit, comprising equipping the mine for production and constructing the railroad and the artificial port, where a breakwater was run out into open ocean 1.9 kilometers. The start of ore exports through the port represented the successful conclusion of the largest industrial project undertaken in Africa to the present time. The project is expected to yield some 300 million tons of direct shipping ore. The cost was some US$220 million. The U.S. company, Raymond International, built the railroad and harbor.

German-Liberian Mining Co. (DELIMCO).—The company is owned equally by the Liberian Government and Gewerkschaft Exploration, largely controlled by the Thyssen interests.[10] Through Bong Mining Co., which will manage the operations, DELIMCO is preparing to mine and concentrate low-grade iron ore situated some 80 kilometers easterly from Monrovia. Besides preparing the mine for production and building a concentrator, the project includes constructing an 80-kilometer railroad to Monrovia and a finger pier at the port. Production of 3 million tons of concentrate per year is expected to begin by the end of 1964 and eventually be increased to 5 million tons.[11]

Liberians are being trained for skilled work both on the job and in West Germany.

Representatives of the West German steel industry who visited Liberia in 1963 stated that when the DELIMCO project is operating, West Germany will become Liberia's largest customer for iron ore. West German firms already have made long-term contracts for Liberian ore.[12]

NONMETALS

Diamonds.—While not recorded, it is known that the diamond production of Liberia has been very small. The substantial exports recorded in recent years have been nearly exclusively diamonds which enter Liberia from adjacent countries (mainly Sierra Leone and Guinea) for sale to buyers in Monrovia. The following official data are for exports by Monrovia diamond buyers (15 in all) during the

[9] Work cited in footnote 4.
[10] U.S. Embassy, Monrovia, Liberia. Dispatch 208, Feb. 23, 1962.
[11] Engineering and Mining Journal. V. 165, No. 1, January 1964, p. 63.
[12] Canadian Mining Journal. V. 85, No. 2, February 1964, p. 164.

Digitized by Google

year ended August 31, 1963, which by value were 13 percent higher than in the previous year:

	Carats	Value, U.S. dollars
Exports:		
Gem diamond	239,555.92	2,976,775.24
Industrial diamond	507,865.15	1,270,603.89
Total	747,421.07	4,247,379.13
Government revenue:		
Royalty collected		637,122.08
License fees		27,708.34
Total		664,830.42

The official values shown, on which royalty is computed, are one-fifth of the price paid by buyers, according to the Bureau of Natural Resources and Surveys of Liberia.[13]

The Director of the Bureau of Natural Resources and Surveys announced that effective January 1, 1964, the President had approved an increase in the price of the diamond-buying license from US$2,500 to US$10,000 per year.

In February 1963 President Tubman dedicated the diamond mine of Liberian Swiss Mining Corp. at Williamstown. It is Liberia's first fully mechanized diamond mine. Swiss capital is largely involved in the venture. The British provided the planning, engineering, management, technicians, and equipment.[14]

The Mineral Industry of Libya

By Taber de Polo [1]

CRUDE oil production has become the backbone of the Libyan economy and is likely to hold that position for many years to come. It accounted for more than 98 percent of foreign exchange earnings to the country in 1963. Libya has become a major source of petroleum supply and has the advantages of relatively low production costs and of accessibility to Western European markets. The reserve was estimated to be from 4 to 8 billion barrels in 1963; new fields were being discovered regularly, and existing fields were being extended. Throughout 1963, the major oil boom continued in this country where 8 years ago there was no positive indication of oil. During the first half of 1963, Libya produced 1.6 percent of the free world crude petroleum and supplied 3.5 percent of total petroleum export trade. This compares with 0.08 percent of total production and 1.9 percent of export trade in 1961—a remarkable expansion considering that the first oil was discovered in June 1959 and that exports did not commence until September 1961.

Employment of Libyans directly related to oil company activity is estimated to have been around 12,500, approximately 4 percent of the paid labor force.

Other mineral activities in Libya included production of minor amounts of lime and salt. Deposits of iron ore, gypsum, magnesite and potash are known.

GOVERNMENT POLICIES AND PROGRAMS

In 1953, the Government of Libya enacted special mineral legislation (Minerals Law No. 9 of 1953) to deal with the few known exploitable mineral resources, primarily petroleum, iron ore, and potash. Separate legislation (Petroleum Law No. 25 of 1955 and subsequent amendments) was enacted for petroleum.

The lowering of tariffs early in 1963 on foodstuffs, industrial machinery, plant equipment, and parts was evidence of the Libyan Government efforts to stimulate foreign trade and business participation—one aspect of the 5-year plan for economic development initiated during the year. Also, in connection with its development plans the Libyan Government adopted a system for registering consulting engineering firms qualified to assist with development projects.

On July 28, amendments to the basic petroleum law were adopted abolishing the Petroleum Commission. Functions formerly exercised

[1] Foreign mineral specialist, Division of International Activities.

Digitized by Google

by the Commission will now be handled by the Ministry of Petroleum Affairs, advised by an interministerial Supreme Council for Petroleum Affairs.

PRODUCTION

Complete and fully reliable data on mineral production in Libya are not available. No production of metalliferous ores or metals has been reported and none has occurred so far as can be determined. Recorded output of nonmetals excludes production of construction materials and salt by local inhabitants for their own use. There has been no production of mineral fuels aside from crude petroleum.

TABLE 1.—Production [1] of minerals

[1] Data are approximate except for petroleum.
[2] Data not available.
[3] Rock for concrete and road construction; apparently includes gravel.

TRADE

In 1963 Libya achieved a surplus in its balance of trade for the first time. For the first 9 months this was more than L£25 million, and oil was almost 99 percent. The total value of imports into Libya in 1962 was L£73,444,000. Total value of exports was L£49,016,000; crude petroleum was L£46,966,000 or 96 percent.[2] [3]

The value of Libya's imports has kept pace with the increasing surplus in balance of trade stemming from oil exports. Oil companies were largely responsible; they imported goods in the amount of L£24,837,000, 34 percent of all imports in 1962.

In 1963 Italy just maintained first place as a supplier to Libya with 20.5 percent of the market. The United States was second with 19.9 percent. Corresponding figures for 1962 are Italy, 24 percent; United States, 19.4 percent.

In May Libya signed a trade agreement with the Communist countries in east Europe that involves, primarily, exporting foodstuffs in return for machinery and textiles.

Early in 1963, Libya, being assured of revenues from oil, substantially cut tariff rates on several items, predominately foodstuffs. High tariffs were continued on luxury goods. Exemption from all duties was granted to agricultural equipment and certain supplies used in agriculture, to petroleum and petroleum development equipment, and to capital equipment for new industries.

COMMODITY REVIEW

METALS

Iron Ore.—In August 1962 a mineral concession was granted for exploration and exploitation of iron-ore deposits of the Shatti Valley, Fezzan. No iron ore has been produced and estimates of potential reserves have not been published.

NONMETALS

Cement.—Raw materials for cement occur in Libya in sufficient quantity for its present needs, but these resources have not been exploited. During the third quarter of 1963, the Industrial Development Organization agreed on a L£100,000-Government contribution towards financing a cement plant in Tripoli. The construction boom in Libya stimulated importation of cement; 1962 imports were valued at L£1,373,605. The completion and operation of this proposed plant should prove a stimulus to Libyan economy.

Gypsum.—During the first half of 1962, the Tripolitanian Provincial Government began construction of a gypsum kiln and fabricating

Digitized by Google

plant a few miles south of Tripoli. It is planned that the facility will use gypsum quarried in the foothills of Tripolitanian western Jebel, and production will be 20,000 tons per year of block and slab for the construction industry. The plant was almost ready to commence production by the end of 1963.

Lime.—Lime production has been slowly but steadily increasing, and the amount in 1962 was almost 20,000 metric tons. During the same period almost half that quantity was imported to meet domestic requirements. With the 5-year plan stimulating local development, and with reserves available, it is to be expected that requirements might be fulfilled locally within 2 to 3 years.

Potash.—In November 1962, the Cyrenaica Government granted permission to a U.S.-backed firm for exploration and exploitation of potash deposits near Marada. These deposits were worked by the Italians during their occupation of Libya before World War II. A successful venture in this field would be an asset to Libya with her present dependence on imported fertilizers.

Salt.—Salt was produced from sea water by a Government monopoly. Operation has been intermitten and large stockpiles frequently have built up. Average annual production is about 15,000 metric tons. Local consumption is 5,000 metric tons. Libya can easily produce enough salt for domestic needs.

MINERAL FUELS

Petroleum.—Production of petroleum during 1963 continued its recordbreaking increase and enabled the 10-year-old country of Libya to achieve a surplus in the merchandise account in its balance of payments. Actually this was accomplished during the first quarter, during which imports totaled L£19.68 million (US$55.1 million), and exports (primarily crude oil), L£23.88 million (US$66.86 million). This occurred despite the import rate having reached a record level.

For the first time in 1963, the merchandise account showed a L£48 million surplus (US$135 million). The value of exports reached L£133,535,000 (US$374 million), while imports stood at L£85,277,000 (US$239 million). Crude oil accounted for almost 99 percent of the value of all exports.

The economic importance of the petroleum industry to Libya lies not only in the Government share of the monies realized from crude oil sales, but also in the large sums spent on exploration and development; a significant part of which accrues to the Libyan Government and her people in wages and other benefits. Expenditures during 1962 by petroleum companies operating in Libya amounted to more than US$200 million, making an accumulated total since 1956 of more than US$800 million. During 1963 the figure went well over the $1 billion mark.[4] Of the 1962 expenditure, about US$80 million was expended for purchases in Libya.

Exports of crude oil in 1963 were two and one-half times the 1962 figure. Continued increases in rates of production and exports are expected before a leveling off is reached.

Exploration and Development.—Drilling operations continued at a record pace during 1963, with from 40 to 45 rotary rigs being active throughout the year. The continued high rate of activity was partially spurred on because concession areas are subject to relinquishment at the rate of 25 percent at the end of 5 years, another 25 percent of original concession area by the end of 8 years, and a third surrender at the expiration of 10 years from the date of grant. Many of these turnback dates occurred in 1963, and companies had to decide what areas they were to relinquish.

During 1963 there were 379 wells drilled, making a total of 983 since drilling commenced in early 1956. Of these 379 completions, 173 were oil producers (overall total, 429) and 206 were dry holes (overall total, 552). Two gas wells have been brought in to date.

The rated daily capacity of producing wells completed in 1963 is 237,532 barrels, raising the figure for all producing oil wells in Libya to 612,280 barrels per day.

The majority of new producers were development or outpost wells in established fields, but 11 of them were listed as discovery wells. The breakdown of discovery wells by companies was: Mobil, four; Oasis, three; CPTL, two; and Amoseas and Phillips, one each.

Geologic and seismic parties continued to be very active, and preparations were underway for offshore drilling to commence.

Areas of Production.—Oil has been found in widely scattered locations in Libya. In each of the four zones into which the country was divided for concession-granting purposes oil has been discovered (Zone 1, Tripolitania; Zone 2, north Cyrenaica; Zone 3, southern Cyrenaica; Zone 4, Fezzan). The 429 producing wells at the end of 1963 were in 25 of the 95 concession areas. Initially, the concession areas amounted to 65 percent of the total land area of Libya, but owing to the surrender procedure the land area covered by concessions was reduced by mid-1963 to a little more than 51 percent—871,152 square kilometers. Marine concessions account for an additional 28,138 square kilometers. The most prolific producing area at present is in the north-central part of the country.

Estimates of reserves range from 4 to 8 billion barrels of oil, and it is likely that discovery of new fields will add to the higher estimated figure.

TABLE 3.—Status of drilled wells

Digitized by Google

Production and Processing Facilities.—There were 25 concession-holding companies and 95 concession areas. Twelve of these companies have developed producing wells. Only three, Esso Libya/Esso Sirte, Oasis, and Mobil/Gelsenberg, had reached the production and exporting stage by the end of 1963. Esso, the first company to export oil from Libya (Sept. 12, 1961), was the producer of the largest volume of oil in 1963. Oasis, the second producing company in Libya (first shipment in May 1962), ranked second in production. The only other company to export oil was Mobil, and it did so through the Oasis pipeline and port facilities.

Refineries.—Esso Sirte completed a refinery at Marsa el-Brega, having a daily capacity of slightly more than 8,000 barrels of finished products. A test run was completed late in the year, and the plant was shut down until product pricing could be agreed upon by Esso and the Libyan Government. Finished products were to include regular gasoline, premium gasoline, kerosine, diesel oil, and residual fuel oil. The plant capacity could meet virtually all Libyan requirements for these basic petroleum products.

Pipelines.—Two major pipelines were put on stream during 1963. Late in January the Raguba field (Esso Sirte and Libyan American) was tied to the Marsa el-Brega port by a 56-mile-long, 20-inch-diameter line. August 3 marked the opening of a 150-mile (mostly 32-inch-diameter) line linking the Oasis oilfields in concession 59 (Cyrenaica) to concession 32 (Tripolitania) and to the port of Ras es-Sidr. Also, Mobil Oil completed a 45-mile gathering system and feeder pipeline for its Hofra field.

Existing lines at the beginning of the year consisted of: the Esso 108-mile, 30-inch line from its Zelten field to its terminal at Port Marsa el-Brega, which started operating in September 1961; the Oasis 85-mile, 30-inch-diameter line from its Dahra field in concession 32 to its port of Ras es-Sidr (started operating in June 1962).

Mobil completed plans for a pipeline connecting wells in concessions 11 and 13 to Ras Lanuf (a new port), and Oasis planned to tie the Geato field in concession 59 to its existing system.

Late in the year Oasis brought the Samah field into its pipeline system.

Port and Storage Facilities.—At Marsa el-Brega (formally inaugurated Oct. 25, 1961), the Esso petroleum port, a bow-mooring device was put into service early in 1963. Not only does this installation greatly increase loading capacity but it enables tankers to load in rough weather, difficult in the two existing offshore berths. A fourth loading line was under construction near the new bow-mooring installation.

Four new storage tanks were under construction during 1963, each with a capacity of 268,000 barrels. This exactly doubled the previous capacity. Eight more similar tanks were contracted to be completed in 1964.

At Ras es-Sidr (formally inaugurated in November 1962) Oasis has two deep-water loading berths 1 mile offshore. Storage facilities consist of 7 tanks, each with a capacity of 313,000 barrels. Plans for three more such tanks were announced in 1963.

The Mineral Industry of the Malagasy Republic

By Thomas G. Murdock [1]

THE MALAGASY Republic (formerly Madagascar) was an important source of high-quality crystalline graphite and phlogopite mica in 1963. Continuation of its chromite exports, begun in 1961, helped to supplement the shortage of this commodity in the franc zone. The Malagasy Republic also made important contributions to French requirements of uranium, quartz crystal, beryl, and monazite. It continued to provide a small market for French crude and finished metals, cement refractories, fertilizers, some petroleum products, and some crude or partly processed minerals.

The economy of the Malagasy Republic is predominantly agricultural. Latest estimates place national annual income at CFAF120 billion [2] (US$489.8 million). The value of the 1962 mineral production at minehead and exclusive of uranothorianite was CFAF613 million. Total mine production on the basis of unit values of exports of individual items and with the official export value of uranothorianite, is estimated at CFAF1,585 million, or about 1.3 percent of the national income.

Mineral exports were a small source of foreign exchange and in 1962 provided only about one-third of the foreign exchange needed for imports of mineral commodities. Employment in the mineral industry, including workers engaged in mica beneficiation, is estimated officially at about 10,250, or 4 percent of all wage earners.

The most significant development of 1963 was the agreement signed in June by the Malagasy Government and five oil companies which will participate in the construction and operation of the 12,000-barrel-per-day petroleum refinery in the country's principal port, Tamatave. It is expected to be in operation by the end of 1965 and to supply all the liquid fuel needs of the Malagasy Republic.

During the year Westinghouse International Corp. conducted an industrial survey in the interest of developing investment projects. The survey included studies of the possibilities of mineral development and industrial production, particularly in the unexploited Sako coalfield in southwestern Madagascar, the lignite deposits in the general vicinity of Antsirabe, and limestone and iron ore deposits near Moramanga.

---

[1] Mining engineer, Division of International Activities.

[2] African Financial Community (CFA) francs are used throughout this country review. The official exchange rate is US$1=CFAF245, or CFAF1=US$0.0040816. On July 1, 1963, the Malagasy Institute of Issue (Institut d'Emission Malgache) officially began functioning and the Malagasy franc (FMG) replaced the CFA franc without change in the exchange rate.

GOVERNMENT POLICIES AND PROGRAMS

A revised mining law which follows the French law in most respects and liberalizes a provisional law effective since September 1960, was promulgated in October 1962. All mineral deposits, except those mined in quarries, belong to the State. Any person, including corporations, may apply for a prospecting permit and a mining permit. Applicants will ordinarily be of Malagasy nationality, but can, under certain circumstances, be of other nationalities. A petroleum code was promulgated at the same time, providing for the granting of a 5-year prospecting permit, renewable twice, to be followed by a 50-year concession in the event of discovery. Profits are to be divided equally between the concession holder and the Government, after certain taxes. The code is designed to encourage oil exploitation.

The Malagasy Government had adopted, in September 1962, an investment code encouraging investment in several categories of enterprises, including mining. The text of this law has been published.[3] In July 1963, an investment guarantee agreement with the United States was signed.

The Government's roadbuilding programs, with financial assistance from France, West Germany, and the European Economic Community, should prove of eventual value to the minerals industry. The United Nations Special Fund inaugurated a project of mineral and ground water investigation in 1963.

SOURCE MATERIAL

Background information for the following sections is from a recent publication,[4] the product of cooperative effort by the Bureau of Mines, the U.S. Agency for International Development, and the Malagasy Republic. Data on output were supplied by the U.S. Embassy, Tananarive, in the annual canvass of world mineral production carried out by the Bureau of Mines and are supported by official publications of Malagasy Government's mineral agency, The Directorate of Mines and Energy. Foreign trade data are from the official trade statistics, published by the Ministry of Finance. In the case of exports, the statistics often differ substantially from the data of the Directorate of Mines and Energy, apparently because a different statistical base is used. The trade statistics are probably based on actual embarkations and declared value and the Directorate data are probably based on sales, supplied by exporters. Where necessary to provide a complete coverage, information from both sources is used. Except for these differences, the information is reliable and complete. A report[5] of the U.S. Regional Minerals Officer has provided complementary current information on activity in the Malagasy Republic.

PRODUCTION

No overall trend was established in output levels during 1959–63. Some minerals were produced for the first time, and production of manganese ore, nickel ore, zircon, and coal was mainly experimental to determine the feasibility of larger operations.

TABLE 1.—Production of metals and minerals

[1] Exports.
[2] Estimate.

TRADE

In 1962, the total value of mineral imports was CFAF3,651 million, 12 percent of all imports and 9 percent above the total in 1961. The 1962 import value, by categories, follows: Metals CFAF1,510 million; nonmetals CFAF630 million; and fuels CFAF1,511 million. Three items accounted for 93 percent of the imports, on basis of value, petroleum products (41 percent), rolled steel products (37 percent), and cement (15 percent).

The Directorate of Mines and Energy reported that mineral exports, including scrap metal, were valued at CFAF1,360 million in 1962 and in 1961 CFAF1,180 million.[6] In 1962, minerals constituted about 6 percent of all exports. Combined exports of graphite, uranothorianite, and phlogopite mica were valued at CFAF1,152 million, 85 percent of the total.

France maintained its position as the principal trading partner of the Malagasy Republic. In 1962 it supplied 56 percent of all mineral imports and received 49 percent of all mineral exports; the United States supplied only 2 percent, practically all petroleum products. However, the United States ranked second as a customer, receiving 22 percent of Malagasy exports, chiefly mica and graphite. Mineral

[6] Foreign Trade statistics, which do not identify uranothorianite exports but include exports of scrap metals, show totals of CFAF1,032 million in 1962 and CFAF1,152 million in 1961.

Digitized by Google

exports to the United States amounted to CFAF315 million and were 9 percent of all Malagasy exports to that destination.

TABLE 2.—Exports of metals and minerals

(Metric tons)

Commodity [1]	1961	1962	Principal destinations, 1962
Metals:			
Beryl	840	725	France 402; United States 304.
Chromite	5,004	19,007	All to France.
Columbite-tantalite	14	7	United States 5.
Copper, scrap	230	336	West Germany 227; Italy 25; France 13.
Iron and steel, scrap	13,356	111	Italy 110.
Lead, scrap	3	10	All to France.
Nickel ore	2	100	Do.
Scandium ore	29	----	
Thorium minerals [2]	784	951	Do.
Zinc, scrap	3	----	
Zircon	----	3	Do.
Other [3]	54	63	Do.
Nonmetals:			
Garnet, industrial	101	77	United Kingdom 75.
Gem stones, semiprecious	9	5	All to France.
Graphite	14 890	16,463	United States 4,984; United Kingdom 3,751; France 2,752; West Germany 2,487.
Mica	1,232	1,086	United States 319; West Germany 208; Japan 161; Belgium-Luxembourg 145.
Quartz crystal	24	22	France 21.
Other	32	10	Islands in the Antarctic 7.
Salt	2,373	1,332	Comoro Islands 741; Reunion 580.

[1] Other commodities were re-exported as follows: fuels, 1961 (50) and 1962 (261); rolled steel products, 1961 (146) and 1962 (86); and, nonferrous metals, 1961 (1) and 1962 (105).
[2] May include some uranothorianite as well as monazite. Directorate of Mines and Energy report exports of monazite as 463 tons in 1961 and 578 tons in 1962. Exports of uranothorianite are reported as 410 tons in 1961 and 544 tons in 1962. All exports of both minerals were to France.
[3] Includes some titanium minerals and perhaps some zircon in 1961.

Source: Statistiques du Commerce Exterieur de Madagascar (Foreign Commerce Statistics of Madagascar), 1961–62.

COMMODITY REVIEW

Consumption of mineral commodities in the Malagasy Republic corresponds closely to imports. In some cases, however, large differences in imports of some commodities from one year to another may indicate a stock buildup, perhaps due to buying in large quantities at a favorable price. Comparison of imports of 1961–62 with those of earlier years indicates slight increases, corresponding to a growing consumption, in such items as rolled steel products, petroleum products, and cement. Of the minerals exported, practically none are used domestically.

METALS

Beryl.—Production of beryl started in 1950 and totaled about 6,300 tons at the end of 1963; beryllium oxide content was 10.0 to 13.5 percent. Although beryl-bearing pegmatites are found from the northern extremity of the island, around the Daraina field, to the Itrongay in the south, the industrial variety occurs only with potassic pegmatites and the sodalithic pegmatites contain only small quantities of gem material.

Chromite.—Chromite mining began in mid-1961. All production has been from the Ranomena mine of Société d'Électro-Chimie, d'-Électro-Métallurgie et des Aciéries Electriques d'Ugine (UGINE), an important French industrial concern. The property, 37 kilometers by road north of the port of Tamatave, includes a number of lenses which are being mined on the surface with bulldozers and power shovels. Three of these contain an estimated 80,000 tons of chromite and about seven others contain a total of 20,000 tons. The stripping ratio is about 4:1. Only the decomposed ore in the upper parts of the lenses, which contains 40 to 42 percent chromic oxide (Cr_2O_3), is mined. The harder chromite below, representing about another 150,000 tons, contains only about 30 to 35 percent Cr_2O_3. The ore being mined contains 2 to 3 percent silica (SiO_2) and has a chromium to iron ratio of 1.5:1.7. The average f.o.b export value of Ronomena chromite was equivalent to $12.96 per ton, according to published foreign trade statistics.

Ugine has explored chromite deposits in the Andriamena area, 180 kilometers north of Tananarive. This work indicates the crude ore contains an average of 38 to 40 percent Cr_2O_3, although rich zones carry 40 to 41 percent. Concentration to 48 percent and a chromium to iron ratio of 2:1 is believed possible. Despite a reserve of 2 million to 3 million tons, the reluctance to use concentrates makes this somewhat unattractive. The chief obstacle to the development of the deposits in the Andriamena region is their remoteness; a 120-kilometer road would have to be built to the branch railway which runs north to Lake Alaotra from Moramanga on the Tananarive-Tamatave line. The high cost of this road and the nature of the deposit have held back development. Thus far, these disadvantages have outweighed the favorable factors, such as Ugine's interest in having their own source of supply and the desire of the Malagasy Government to encourage economic development.

Monazite.—The increasing production of monazite has been an important development of recent years. All output has been from beach sands near Fort Dauphin. Three major deposits of old dunes are known, in addition to others of noncommercial quality north of Foulpointe. The deposits near Fort Dauphin are at Antete, Vohibarika, and Ialanmainty. Only the first of these has been worked.

The major producer of monazite is the Société de Traitement des Sables du Sud de Madagascar (SOTRASSUM) which was established as a joint venture by the French Atomic Energy Commission (Commissarait a l'Énergie Atomique or CEA) and the Compagnie des produits Chimiques Pechiney (Pechiney). The CEA takes the thorium content, while Pechiney takes the rare earths contained in the monazite.

SOTRASSUM has been mining an old dune deposit at Antete, 40 kilometers southwest of Fort Dauphin, since 1959. Nearly 4 million tons of sands has been proved by close drilling and sampling, averaging 2.00 to 2.55 percent monazite and about 50 percent heavy minerals, including ilmenite and zircon. In 1963, only the monazite was marketed and the ilmenite and zircon were stockpiled at the plant.

Digitized by Google

Monazite also was mined from beach sands at Fort Dauphin by Société d'Eploitation des Monazites, a subsidiary of Etablissements Tricot, manufacturers of lighter flints in Paris The treatment plant had a capacity of 200 tons of monazite per year, but in 1963, it produced only a fraction of that. At yearend the plant was being moved to Vohibarika.

Nickel.—Investigations have been in progress by the Malagasy Geological Service, the French Bureau de Recherches Géologiques et Minières, and Ugine of the potential nickel resources of the Malagasy Republic. Earlier, efforts to develop the small, low-grade deposits south of Ambositra, classic occurrences of lateritic alteration over periodotites, were unsuccessful. Detailed exploration of nickeliferous laterites around the periphery of the Ambatovy and Analamay ferruginous shields continued in 1963, but results have not been announced. Exploration methods included sample pits and drill holes. The 100 tons exported in 1962 was shipments to France for metallurgical testing. Previously, 35 million tons of lateritic iron ore was proved in the portions of these ferruginous shields inside the areas of nickeliferous laterites.

Uranium.—The Malagasy production of uranium is as uranothorianite, a mixture of uranium and thorium. First exploitation was in 1954 and subsequently the mineral has become the country's second most valuable export. According to the Directorate of Mines, the 1962 exports were valued at CFAF389 million. All exports have been to the CEA plant at Le Bouchet, near Paris.

The uranothorianite occurs as an accessory mineral in pyroxenite lenses in Precambrian rocks; all the economic deposits are within the loop of the Mandrare River, about 80 kilometers due northwest of Fort Dauphin. Mining has been on the surface and overburden has been moderate. At the mines of the CEA, the principal producer, blastholes are drilled with wagon drills and the ore is loaded with front-end loaders into heavy trucks. Most of the pit equipment is of U.S. manufacture. CEA's Ambindandrakemba mine supplied most of the ore until early 1963, when it was exhausted. At that time the nearby treatment plant and the mine town of Ambatomika were closed down and the equipment was moved about 40 kilometers north to Betioky, which is near the ore body, Belafa. The ore reserve at Belafa is estimated at about 2,000 to 5,000 metric tons of uranothorianite (about 100,000 to 300,000 tons of ore), but exploration of the deposit is not complete. The ore body is a typical, almost flat-lying, irregular lens. The ore at Belafa averages about 0.3 percent uranothorianite, ranging from 0.2 to 0.6 percent. At the end of 1963, some ore was being obtained by CEA from three smaller ore bodies near Belafa.

In addition to the operations of CEA, the following four private operators were active during 1963: C. F. Lanoué, Kotovelo (plant at Marovato); Société des Minerais de la Grande Île, Ambatoaho mine; Société d'Exploitation des Mines d'Andrananondambo, Bevalala mine; Société Minière et Forestière, Betanimera.

The CEA will provide a stable market until 1970. The contracts under which the CEA purchases uranothorianite from the small producers offer CFAF2,850 per kilogram of uranium metal content and

Digitized by Google

CFAF350 per kilogram or thorium for ore high in thorium; in other ores the contracts call for CFAF5,000 per kilogram of uranium and CFAF100 per kilogram of thorium, less CFAF225 per kilogram purchased.

NONMETALS

Graphite.—The Malagasy Republic possesses virtually inexhaustible reserves of excellent quality flake graphite. Graphite production has been an established industry since 1907 and has survived several economic crises. Graphite has been the country's principal mineral export. Malagasy graphite has found a wide market and its quality and reasonable price have made it popular with users of crystalline-flake graphite throughout the world.

The specifications for crucible-grade graphite have changed considerably during the last 6 years, and exports which earlier comprised a greater tonnage of flakes than of powder now consist increasingly of fine product for which buyers demand higher carbon content. The decline in the demand for flakes is reflected in the reduced proportion of these in total exports, from 41 percent in 1958 to 35 percent in 1962. Comparative annual export values per ton for the two, as reported by the Directorate of Mines and Energy, follow:

	CFA francs		Percent increase
	1958	1962	
Flake	26,796	28,459	6.2
Fines	17,943	23,202	29.3
Average	21,543	25,032	16.1

The producers active in 1963 and their production in 1960 and 1961 follow:

Company	Mine	Production (metric tons)	
		1960	1961
Établissements Gallois	Antsirakambo	2,780	6,773
	Marovintsy	2,340	
Établissements R. Izouard	Falariano	2,524	2,933
Compagnie Lyonnaise de Madagascar	Ambatomitamba	1,544	2,014
Société A. Louys et Compagnie	Andasifahatelo	927	1,768
Établissements G. Rostaing	Sahamamy	917	918
Syndicat Lyonnais de Madagascar	Tromoina	----------	475

In late 1963, Société Malgache des Exploitations Minières resumed operations at the Ambalarondra mine in the Brickaville area, closed since November 1960.

Mica.—The Malagasy phlogopite mica deposits are northwest of Fort Dauphin, in numerous pegmatoid veins and occasional pockets, irregularly distributed in beds of pyroxenite which usually are inter-

Digitized by Google

stratified in the crystalline schists between Ihosy and Fort Dauphin. With the termination of U.S. stockpile purchases in July 1963, several mines shut down and employment in splitting shops dropped to about one-third of the earlier figure.

The average f.o.b. value of mica exports in 1962 compares with that of selected years as follows:

	CFA francs per kilogram		
	1956	1959	1962
Block	713	851	602
Splittings	216	278	363
Average	254	316	379

In 1962, about 15 mines were in operation. Exploration with accessory production was carried out in about 20 additional areas. The major producing companies and mines in 1962 and their 1961 production follow:

Company	Mine	1961 (metric tons)
Société des Minerais de la Grande Île	Benato	400
Union des Micas	Ampandrandava, Sakasoa	173
Établissements W. Boetschi	Sakamasy, Ambatomena	166
Société Malgache d'Exploitations Minières	Maflefy	109
Les Fils de C. Jenny	Vohibola	80

MINERAL FUELS

Coal and Lignite.—Despite the existence of the Sakoa coalfield, extending over more than 100 kilometers in the central Onilahy River region in the southwestern part of the country, Malagasy's small requirements of coal and lignite have continued to be met by imports. The Sakoa field contains 60 million tons of noncoking bituminous coal with an ash content of 17 percent. Some experimental mining has been conducted, but high mining costs, the absence of local markets, high cost of transport to the sea, and high coastal shipping rates have combined to discourage development. Lignite deposits adjacent to the railroad between Tananarive and Antsirabe also have been investigated, but the limited thickness of the seams and low calorific value have limited utilization to times of emergency. The 1963 investigations of Westinghouse International Corp. were directed particularly towards an appraisal of economic possibilities for the domestic solid fuel resources.

Petroleum.—There is no crude petroleum production in the Malagasy Republic, although persistent efforts to discover petroleum have been made since before World War II. Since 1947, work has been concentrated in two sedimentary basins along the west coast. These are the

Digitized by Google

Morondava Basin, between Morondava and Cape Saint André, where 10 years of geophysical work and about 30 drill holes proved unfruitful; and the Majunga Basin, from Cape Saint André to Diego Suarez. The French Société des Petroles de Madagascar (SPM) holds exclusive exploration and exploitation rights and reports expenditures of CFAF5,880 million on the Morondava Basin. Current expenditures are about CFAF320 million annually on exploration in the Majunga Basin.

At Bemolanga, near Morafenobe in the Morondava Basin, exploration has indicated the existence of bituminous sandstones estimated to contain 1 billion tons of bitumen. In 1963, SPM continued earlier investigations of the economic feasibility of exploiting these deposits commercially. Participation of SPM in construction of the Tamatave refinery indicates that for the time being no development of the bitumen is envisaged.

SPM will have the largest interest in the Tamatave refinery. The marketing companies, Caltex, Esso, Shell, and Desmarais Frères, will participate in shares proportional to their share of the market. Late in 1962, an Italian group, Azienda Generale Italiana Petroli (AGIP), obtained permission to import and distribute its petroleum products in Madagascar and formed a subsidiary, AGIP—Madagascar, capitalized at CFAF40 million. The new company reportedly agreed to make substantial investments in the country.

The Mineral Industry of Mauritania

By Thomas G. Murdock[1]

BOTH the former French Administration and the present government of the Islamic Republic of Mauritania stressed the search for and development of the country's mineral resources as part of their efforts to diversify the economy. However, mining occupied an insignificant role until 1963 when facilities for exploitation of the extensive high-grade iron ore deposits near Fort Gourand were completed and the first shipments of ore to Europe were made, marking an important step in Mauritania's attainment of economic viability. The revival of interest in the country's copper deposits was also a significant event of 1963.

Recent data on Mauritania's gross domestic product (GDP) are not available. In 1958, the GDP was US$65 million (CFAF16,042 million).[2]

In 1962 the value of the mineral production was limited to an estimated CFAF2 million worth of salt plus a small value for an unrecorded quantity of gypsum, excluding the iron ore stocked for export pending completion of railroad and port construction. In 1963 the value rose to approximately CFAF2,888 million. Expectations were that with the planned increase of iron ore exports, the contribution of the mines to the economy would rise to CFAF8,885 million in 1964, gradually working up to CFAF13,327 million when full capacity is achieved. A favorable market was assured because the shareholders in the mining enterprise include a number of major European steel producers. According to rough estimates, by 1967 the government will be receiving about CFAF1,974 million as its 50 percent share in the profits plus about CFAF494 million annually as income taxes and customs revenues. This income should provide about one-third of the total revenue for the Mauritanian budget and permit the renunciation of all French budgetary support.

Data on employment in mining are not available. Assuming that one-third of the inhabitants of the iron mining company's newly constructed camps are employees, about 1,500 are employed in the mines and 1,000 in the port. Considering that wage earners in the country number only about 18,500 and of these 6,700 belong to the public sector, the iron ore development is of major importance as an employer, despite the extensive mechanization of operations. Over 90 percent of the country's economically active population earn their livelihood from pastoral and agricultural pursuits; total population is estimated at only 770,000 although some official sources place this as probably closer to 2 million.

[1] Mining engineer, Division of International Activities.
[2] African Financial Community (CFA) francs are used. For Mauritania the exchange rate used is US$1=CFAF246.8 (CFAF1=US$0.004052).

GOVERNMENT POLICIES AND PROGRAMS

No legislative changes affecting the mineral industry were reported in 1963. The basic laws regulating private foreign investment remained in effect; these are the Long-Term Investment Code for Iron Ore Concessionaires as embodied in the law of July 10, 1959, and subsequently amended in 1959 and 1960; the Petroleum Code of June 12, 1961; and the Investment Code of June 26, 1961.

The basic financial agreement between the iron mining company and the Mauritanian Government was that there shall be a straight 50–50 sharing of net profits. In order to insure an income to the government before the first net profits are realized (several years after ore shipments started), the agreement called for the government to receive 6 percent of the gross value of ore embarked at Port Etienne beginning with the first shipment. Such payments are to be deducted from amounts later credited to the government under the equal profit-sharing scheme.

At the official inauguration of the iron mining complex, the president of Mauritania renewed his assurance that the government's commitment towards foreign investors, for which legitimate guarantees will be provided, will always be respected.

The Petroleum Code provides for a sliding scale of royalties on oil and gas production; the 50–50 profit-sharing principle and a 27.5 percent depletion provision are included.

During 1963 work was continued on the construction of the Nouakchott wharf on a coastal dune about 8 kilometers west of the Mauritanian capital. Completion of this and other port improvements, scheduled for about mid-1964, will allow an annual unloading capacity of about 100,000 tons; it will provide an outlet for copper ore from the Akjoujt deposits and permit further exploitation of titaniferous sands and gypsum deposits. Cost of the current first phase development was placed at about CFAF 457 million.

SOURCE MATERIAL

Dispatches of the U.S. Embassy in Nouakchott provided the information on production and 1963 developments. Background data are from a current U.S. Government publication.[3] For several years the technical press has reported the development of the iron mines and a complete detailed account of the mines and facilities appeared in a French journal.[4] The limited data on trade are from a French Government publication, which is the only available source and which lacks completeness and detail.

PRODUCTION

Mauritania's only recorded mineral production in 1959–61 has been of iron ore and salt. Since the beginning of iron ore production in 1960 this has increased annually to permit large-scale exports as soon as transportation facilities were completed. Salt production is only

[3] Hutt, William E. Basic Data on the Economy of the Islamic Republic of Mauritania. U.S. Department of Commerce. Overseas Business Reports. No. OBR–63–6, January 1963. 14 pp.

[4] Mines. (Paris). Special MIFERMA Number. V. 18, No. 108, 1964, pp. 342–391.

Digitized by Google

an estimated figure and has usually fluctuated from year to year depending upon local demand; the exports to neighboring countries had ceased previously.

Construction materials of domestic origin have been extensively used in the completion of the facilities for iron mining and transportation and also in building at Nouakchott, the new capital city, to provide for an initial population of 6,000 inhabitants; however, no data on quantities produced or consumption are available.

TABLE 1.—Production of metals and minerals

Commodity [1]	1959	1960	1961	1962	1963
Metals:					
Iron ore thousand metric tons	----------	----------	300	1,000	1,300
Nonmetals:

[1] Gypsum and other building materials have been produced but no quantitative data are available.
[2] Estimate.

TRADE

Prior to 1963, exports of metals and minerals had been limited to small quantities of salt, sample lots of copper and iron ores for experimental purposes, and perhaps some scrap metals and imported petroleum refinery products. This situation changed significantly in 1963 when exports of iron ore were made for the first time. Valued at about CFAF2,777 million, these constituted 69 percent of the value of all exports, estimated at about CFAF4,028 million on the basis of data through September (CFAF687 million in 1962 and CFAF432 million in 1961). Of the 1963 iron ore exports of about 1,250,000 tons, France was the leading recipient (about 412,500 tons and CFAF916 million), followed by Italy (about 287,500 tons and CFAF639 million), West Germany (about 262,500 tons and CFAF583 million), and the United Kingdom (about 212,500 tons and CFAF472 million).

Data on imports of metals and minerals are not available in complete detail for 1962; however, total value for items recorded was CFAF3,257 million (CFAF2,514 million in 1961). Imports of these commodities constituted 37 percent of all imports in 1962 (33 percent in 1961). Neither are data available on the sources of the metals and minerals imports; as France supplied 73 percent of all 1962 imports, the former probably came mainly from that country. The European Economic Community, of which Mauritania is an associate member, supplied an aggregate 78 percent of the total and the United States, 10 percent.

The 1963 imports of minerals and metals had an estimated value of CFAF1,109 million; the decrease over the preceding years was due mainly to the termination of construction work incidental to the bringing into production of the Fort Gourand iron ore deposits and on supporting infrastructure.

Digitized by Google

TABLE 2.—Principal imports of metals and minerals [1]

Commodity [2]	Quantity (metric tons)		Value (millions CFAF)	
	1961	1962	1961	1962
Metals:				
Iron and steel [3]	[4] 67,327	90,938	2,166	2,865
Other metals [3]	174	163	42	37
Nonmetals:				
Cement and lime	28,330	29,842	120	128
Salt	18	23	1	1
Mineral fuels:				
Petroleum refinery products	15,248	22,248	185	226
Total	111,097	143,214	2,514	3,257

[1] Data on sources are not available; France was undoubtedly the leading supplier.
[2] Data on other items imported are not available, nor is a further breakdown possible.
[3] Mostly rolled products but may include small quantities of pig iron.
[4] Includes 62,156 tons of rails in 1961 and probably a similar proportion in 1962, thus representing an abnormal volume of imports for specific construction subsequently completed.
[5] Includes an unstated quantity of manufactures.

Source: Institut National de la Statistique et des Études Économiques (Paris). January–March 1964.

COMMODITY REVIEW

METALS

Copper.—The year saw a revival of interest in the Akjoujt copper deposits. Negotiations were begun between Northfield Mines, Inc., a Canadian-American concern, and the Mauritanian Government. Expectations were that these would be successful and that the Lindsley and Homestake groups composing Northfield would have a controlling interest, with a respective participation of 27 and 28 percent, respectively; the Mauritanian Government would have a 25-percent holding and the remainder would be in the hands of some of the former owners of Société des Mines de Cuivre de Mauritanie (MICUMA), an association of the French Bureau de Recherches Géologiques et Minières, Société Minière et Métallurgique de Penarroya, the Banque des Paris et des Pays-Bas and private shareholders.

This new effort followed three previous attempts to exploit the deposits, about 270 kilometers north of Nouakchott and estimated to contain about 18 million tons of sulfide ore averaging 1.5 percent copper and 0.008 ounce of gold per ton and 7 million tons of oxide ore averaging 2.9 percent copper and 0.095 ounce of gold per ton. Tests carried out in the United States on samples of Akjoujt ore proved satisfactory and reportedly an annual production of 10,000 tons of copper and 30,000 ounces of gold might be possible. Cost of the project was estimated at about CFAF3,973 million. However, even with an early agreement and the ratification of this by the Mauritanian legislature, commercial production is not expected until after further metallurgical tests have been carried out, probably about 1966.[5]

Iron Ore.—Early 1963 saw the completion of the iron ore project of Société des Mines de Fer de Mauritania (MIFERMA), several months ahead of schedule. The necessary operations included opening up the extensive high-grade deposits near Fort Gourand in northern

[5] Mining Journal (London). Mauritania Copper Development. V. 262, No. 6711, Apr. 3, 1964, p. 253.

Digitized by Google

Mauritania, construction of the 1.44-meter gage railway across forbidding desert to Port Etienne on the Atlantic 650 kilometers away, and the installation of the modern ore-loading facilities there. The first shipment from the mines was made on April 12, and the first ship was loaded on April 27.

MIFERMA, an international company, was established in 1952 and capitalized at CFAF13.3 billion, distributed approximately as follows: Bureau de Recherches Géologiques et Minières (a French Government organization), 24 percent; French financial groups, 22 percent; French steel interests, 10 percent; British steel interests, 19 percent; Italian steel interests, 15 percent; West German steel interests, 5 percent; and the Government of Mauritania, 5 percent. Financing included a World Bank loan equivalent to about CFAF16.3 billion and other loans amounting to CFAF7.4 billion.

The deposits are near the Mauritania-Spanish Sahara border, in the Kedia D'Idjil, a low mountain range in the form of a triangle which covers about 220 square kilometers and rises about 600 meters above the surrounding Saharan plain. Latest ore reserve data place 125 million tons in the proven category and 75 million tons as probable. The average iron content of the mineralized masses comprising the economic orebodies is 64 percent, ranging between 55 and 70 percent. The iron content of the enclosing rocks, ferruginous quartzites perhaps comprising an additional billion tons of reserves, is 40 percent. An average analysis of the first quantities of ore mined was iron, 65.6 percent; silica, 3.25 percent; alumina, 0.83 percent; phosphorous, 0.03 percent; carbon, 0.06 percent; and moisture, 0.25 percent.

The area of known mineralization consists of several individual deposits, each showing different characteristics. F'Derik, to the west, contains compact ore; the ore in Tazadit to the east and in Rouessa in the center is more friable. All deposits are exploitable by opencut, and actual mining of the Tazadit started in 1961 and continued on an increasing scale as fast as stripping permitted the development of faces. Through the end of July, 1,337,000 tons of ore had been mined; in this way stocks were built up pending the completion of the railway. Additional tonnages moved were 2,429,000 tons of waste and 442,000 tons of low-grade ore set aside for possible later beneficiation.

Open pit equipment at Tazadit included nine 2 to 6 cubic meter capacity shovels, served by sixteen 27-ton and twenty-two 65-ton dump trucks. This equipment permits mining annually 4.5 million tons of ore and stripping 9 to 10 million tons of waste. The F'Derik deposit is to be equipped to produce 1.5 million tons of ore per year and in 1963 an initial production of float ore covering the flanks of the hillside began; mining was by the bulldozers. The installations at Tazadit include a 188-centimeter by 137-centimeter gyratory crusher, a 1,800 tons-per-hour capacity belt conveyor system to carry ore to the stocking bridge, a 3,000 tons-per-hour bucket-wheel excavator to reclaim stocked ore, and another conveyor to carry ore to 800-ton silos equipped for loading railway cars at the rate of 4,800 tons per hour.

The rolling equipment of the railroad includes twenty 2,000-horsepower traction diesel locomotives and 650 cars of 75 tons net capacity each. The pier at the port is 244 meters long with a water depth of 12 meters which can be dredged to 15 meters. Storage facilities for

Digitized by Google

1 million tons of ore are available, and the original ship-loading installation has an hourly capacity of 3,000 tons, subsequently to be doubled; ore carriers of up to 60,000 tons can be handled. Electric power, generated by diesel engines, is provided by two 1,100-kilowatt units and four 2,260-kilowatt units at the mine and eight 1,000-kilowatt units at the port. Modern industrial cities have been built for staff and workmen at Zouerate near Fort Gourand and at Cansado near Port Etienne.

By November average daily transport of ore by the railroad was 12,000 tons. This level was lower than originally anticipated, being barely sufficient to handle the 4 million tons of ore scheduled for export in 1964 and clearly insufficient for the 6 million tons scheduled for 1970. Transport difficulties have been caused by heavy sand penetration into the working parts of locomotives and abrasive action on the cars. Strike difficulties at Port Etienne in late 1963 caused practically no interruptions to operations because the facilities are highly mechanized. At yearend a secondary crushing and screening plant was being installed at the port to improve MIFERMA's competitive position in a buyer's market and to permit marketing run-of-mine ore or products specifically for sintering plant, blast furnace, and open hearth use.

Titanium.—Black sands occur in large quantity along the Mauritanian coast; reportedly they contain economic amounts of ilmenite, with associated zircon, and are thus similar to the Senegalese deposits which are exploited. The Mauritanian Government reportedly envisages the exploitation of the black sands once the port improvements underway at Nouakchott are completed. Exploration has proven 4 million tons of mineralized sands containing 250,000 tons of ilmenite assaying 52 percent.

NONMETALS

Gypsum.—Although gypsum deposits 0.50 to 2.50 meters thick and containing an aggregate of 17 million tons are known in an area 70 kilometers north of Nouakchott, these have been exploited only on a small scale. Investigations have revealed that the gypsum has similar characteristics to the gypsum of the Parisian basin, and a high quality plaster results from its calcination. A small calcination plant has been built and the product used in finishing buildings in the capital city. A larger production is expected to be possible when Nouakchott port development is completed.

Salt.—In 1963 rock salt production was continued on a scale slightly above that of the immediately preceding years. Two mines were worked, by primitive opencut, at Adrar near Fort Gourand and at N'Teret, to the north of Trarza. Salt production during recent years has remained at less than one-quarter of what it was a decade ago as a result of discoveries in Senegal and Mali, which were formerly the two principal markets. Expectations of an increased local demand have risen from the possibilities of the development of the Akjoujt copper deposits, because the segregation process suggested for use in the treatment of the oxide ores there would require a considerable quantity.

MINERAL FUELS

Petroleum.—Reportedly unsuccessful exploration for petroleum was continued in several areas by the foreign companies holding permits. The following companies held valid permits: Société Africaine des Pétroles (SAP); Société de Participations Petrolieres (PETROPAR); and, Société des Pétroles de Valence. SAP explored the Nouakchott area where its program called for the expenditure of CFAF1,481 million over a 5-year period. PETROPAR was active near Port Etienne where plans were to spend CFAF1,974 million. Programs of expenditures planned by the other companies had not been announced.

Despite the unsuccessful efforts in past years, at the beginning of 1963 it was thought that petroleum might exist in the sedimentary basin of the Senegal River and the Tindouf and Taoudini synclines. The Senegal River stretches over about 65,000 square kilometers along the coast, from the estuary of the Senegal to the Spanish Sahara border. The Tindouf syncline covers an area of 3,500 square kilometers in the northern part of the country, and Taoudini syncline is in eastern Mauritania.

A slightly decreased consumption of petroleum refinery products is reflected in the indicated imports through November; these were at the annual rate of 21,818 tons, 2 percent below that of 1962.

The Mineral Industry of the Kingdom of Morocco

By Thomas G. Murdock [1]

OUTPUT of some Moroccan minerals was well below the level of immediately preceding years, but substantial gains in the production of coal, phosphate rock, and petroleum occurred. As in 1962, the industry was confronted with low world demand, declining reserves, rising costs, and labor problems. Although relatively small, the decline in output of several major commodities since 1961 marks a significant reversal of the upward trend in production over the previous decade. Mining remained the largest single industry in Morocco, and minerals constituted the largest major class of export. Agricultural activities occupied most of the labor force and less than 1 percent of the total labor force of about 3.3 million was engaged in mining and petroleum production; employment in these sectors totaled 32,200 at the beginning of 1963 and decreased by 7 percent to 29,800 by yearend.

Morocco ranked second only to the United States in production of phosphate rock, and as the traditional world leader in exports, continued to set production standards and fair trade price structure. The country has produced about 10 percent of free world cobalt supply during recent years. In 1962 Morocco ranked sixth in world manganese production, but in 1963 it lost this place to Gabon. Phosphate rock continued to be exported widely, and other minerals helped supply the growing needs of Western Europe. Exports to the United States in 1963 were principally barite and manganese ore.

In 1962 the Moroccan gross national product (GNP) was DH9,943 million [2] (US$1,965 million). In that year, total value of mineral production was DH709 million, or 7.1 percent of the GNP. Moroccan mining companies, exclusive of the Government-owned Office Cherifien des Phosphates (OCP), had an aggregate capitalization of approximately DH227 million, of which DH76 million was held by the Government's agency, Bureau de Recherches et de Participations Minières (BRPM).

During 1963 satisfactory progress was made on the construction of the chemical complex at the port Safi, a venture of OCP, BRPM, and another quasi-governmental body, Bureau d'Études et de Participa-

tions Industrielles (BEPI). In October a Moroccan press announcement [3] stated that major changes in the original plans will reduce the total cost of this project from DH500 million to DH278 million. Scheduled for completion in 1965, the installations are expected to produce annually 200,000 metric tons of triple superphosphate, 150,000 tons of diammonium phosphate, 36,000 tons of ammonium nitrate, 350,000 tons of 65 percent iron pellets, and 2,700 tons of copper. Twenty-five thousand tons of the 435,000 tons of sulfuric acid produced will be marketed. Raw material consumption is to be 561,000 metric tons of phosphate and 470,000 tons of cupriferous pyrrhotite from domestic mines, and 51,600 tons of imported ammonia. The Government's intention to call for bids for the construction of the ammonium phosphate unit at Safi was announced in April.

Labor unrest characterized a substantial part of the first half of 1963. The Zellidja lead mines, strikebound for 3 months, were the hardest hit. Short sympathy strikes resulted in some lost production from other mines. The unions were unable to attain their main objective, to prevent further layoffs; but they gained generous separation terms for workers being discharged. The agreement ending the Zellidja strike was significant in that the union recognized that management could discharge personnel in order to achieve efficient operations. In 1963 the nation's largest union, Union Marocaine du Travail (UMT), maintained its dominant position in the mining industry. UMT reacted to the unemployment problem by demanding nationalization of the mines. In March UMT found support from the Istiqlal Party press, which pointed out that two successful mining cooperatives were in operation in Tafilalet and Quarzazate. In May, Morocco signed an agreement under which West Germany will be permitted to recruit unemployed Moroccan mine labor.

The border conflict with Algeria, in the fourth quarter, had no direct effect on Morocco's foreign trade. The frontier remained open, and Moroccan exports from the Oudja area continued to be shipped through the Algerian port of Nemours.

Freight rates to and from European ports were scheduled to increase by 10 percent on October 15.

GOVERNMENT POLICIES AND PROGRAMS

No significant mining legislation was enacted in 1963. The Moroccan Government continued to play a major role, directly or indirectly, in the entire mineral industry, through ownership of OCP; and BRPM not only serves as a promotion and holding company but also engages in exploration and development activities. The Government emphasized the need for developing new sources, either through extending deposits already being exploited or through finding new ones. Both Government agencies and private companies were active in this program. Perhaps the most notable items in this respect were the several separate concessions for petroleum prospecting, to be undertaken by foreign firms in cooperation with BRPM. The Gov-

[3] Marco Informations (Rabat, Morocco). Oct. 8, 1963, p. 4.

Digitized by Google

ernment's efforts to promote the training of Moroccans for professional work in the mining industry began to bear fruit in 1963.

To assist the hard-pressed mining industry, in 1963 the Government undertook a further reduction of export taxes and continued rebates on power charges. A decree of April 16, 1963, retroactive to July 1, 1962, established a new schedule of export duties under which all mineral products pay only 0.5 percent ad valorem, except phosphate rock, manganese ore above the first 6,000 tons extracted annually from a single mine, and iron ore. The exceptions still pay the 5-percent duty established in 1959. Rebates in power were granted to the industry, except for phosphates and iron ore, amounting to DH0.02 per kilowatt-hour for electricity and DH0.15 per liter of diesel oil.

In 1963 efforts to further diversify the list of Morocco's trading partners were continued. Existing trade agreements requiring renewal were extended or amended and several new ones were negotiated; all of these include mineral commodities. Communist countries were well represented in the list of agreements signed.

SOURCE MATERIAL

Information is obtained mainly from the Foreign Service dispatches of the U.S. Embassy at Rabat and the Consulate General at Casablanca, supplemented by several publications of the Moroccan Government. The latter's official foreign trade statistics for some commodities differ from those indicated by the Direction des Mines et de Géologie. Except for a few items, the former have been used in order to have a complete coverage of all commodities. Preliminary data for 1963 are used in some cases; these are based on totals shown in Note de Documentation, a monthly publication of the Sub-Secretariat of State for Commerce, Industry, Mines and Merchant Marine.

PRODUCTION

Although output of several major minerals was lower than in 1962, the general level compares favorably with 1959; the increases for phosphate rock, petroleum, and several other items over the 1959–63 period were substantial. Both world market conditions and Moroccan internal developments have contributed to these changes in production levels. Official production indexes show that through October average monthly production, exclusive of fuels, was 5 percent below that for all of 1962 but still 8 percent above that for all of 1958. Exclusive of phosphate rock, it was 20 percent below that of 1962 and 21 percent below that of 1958.

[1] Estimate.
[2] Final figure: supersedes figure given in commodity chapter, volume I.
[3] Includes refinery fuel and losses, except in 1963, when they are not reported separately.

TRADE

Mineral exports were valued at DH676 million in 1962 (DH682 million in 1961). In 1962 they were 38 percent of all exports in terms of value and 84 percent in terms of quantity. Exports of phosphate rock alone were valued at DH436 million; phosphate rock, manganese ore, lead ore and metal, and iron ore comprised 92 percent of the total value of mineral exports.

In 1962 the total value of mineral imports was DH136 million, 7 percent of all imports and 31 percent below the DH211 million total in 1961. This decrease was due entirely to the increased output of the domestic petroleum industry. The 1962 import values of minerals were: metals, DH48 million; nonmetallic minerals, DH13 million; and mineral fuels, DH75 million.

France has continued to be Morocco's principal partner in mineral trade, receiving 27 percent of the exports and supplying 51 percent of the imports in 1962. In that year the share of the United States

Digitized by Google

was only 5 percent of mineral exports, mostly manganese ore, and 3 percent of mineral imports, mainly petroleum products. Mineral commodities comprised 64 percent of all exports to the United States, but constituted only slightly over 1 percent of all 1962 Moroccan imports from the United States.

Preliminary mineral trade data for 1963 indicate that through November exports were 6 percent higher than in the similar period of 1962; imports were about 4 percent lower.

TABLE 2.—Exports of major metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals: [1]			
Aluminum: [2]			
Scrap	1,054	681	Italy 558; France 73; Belgium-Luxembourg 50.
Other	20	83	France 62; Senegal 21.
Antimony ore	1,147	1,014	Spain 590; France 424.

[3] Believed to be mainly lead ore.
[4] Includes bentonite.
[4] Includes andalusite.
[5] Includes cryolite, fluxing stone, fuller's earth, calcined gypsum, limestone, meerschaum, mica, ornamental granules, phosphate rock, quartz, quartzite, crushed stone, slate, and unspecified.
[6] Excludes imports into Ceuta and Melilla (Spanish enclaves), mainly for bunkers. Reported as totaling 6,359,000 barrels in 1961 and estimated at same quantity in 1962.

COMMODITY REVIEW

METALS

Antimony.—Although 1963 antimony production did not reach the 1952 peak of 1,270 metric tons of contained metal, the increase over that of 1962 is indicative of a growing importance of the commodity. No single large deposit has been discovered yet, but over 20 small occurrences are known. Primitive extraction methods have been fol-

Digitized by Google

lowed and high production costs and a highly competitive market have continued to limit production, mainly to the Beni Mezala mine of Société Minière de Beni Mezala southwest of Ceuta and the Timerdouhne mine of Société Moraccaine des Mines et des Produits Chimiques. Exports totaled 1,451 metric tons of ore, estimated to contain 47 percent antimony. Spain was the principal destination with 600 tons, all from Beni Mezala. Omnium Gerance Industrielle et Minière announced plans for additional exploration at their Tourtit and Masser Aman deposits in the Mrirt area which has been idle since 1956.

Cobalt.—Société Minière de Bou Azzer et du Graara, the country's only producer, continued operations at its mines at Bou Azzer in the Anti-Atlas Mountains, at a slightly reduced rate. The mines have been in uninterrupted exploitation since 1932 and the annual cobalt output normally shows quantitative variations, partly due to the irregular mineralization encountered in the underground mining. Exports are as gravity concentrate assaying 12 percent cobalt and 2 percent nickel; these totaled 16,712 metric tons in 1963 (10,304 to France, 4,000 to mainland China, and 2,408 to Belgium). In 1963 exploration was continued at Aghbar, 10 kilometers east of Bou Azzer, reportedly with satisfactory results.

Iron Ore.—In 1963 iron mining, with the lowest production since 1946, continued to center in the Nador area of the former Spanish zone. The Ait-Amar mine in the former French zone, producer of 21 percent of the 1958–60 country total, remained closed during 1963. About 80 percent of the 1963 output came from the two Uizan mines of Compagnie Espagnole des Mines du Rift (CEMR), a Spanish company in which BRPM has had a 26.7-percent participation since 1959. Most of the remainder came from the nearby mines of Société Anonyme Minière Setolazar, a CEMR affiliate. In 1963 total reserves of the Nador area were estimated at about 50 million metric tons. Marketing difficulties and the increased proportion of ore which must be mined underground at Uixan and of pyritic ore which must be roasted at both properties combined to limit production. Demand for Moroccan ore has continued to decline because of competition from other producers of comparable grade ore favored by lower freight rates through the use of new, large ore-carrying vessels. The Moroccan producers endeavored to improve the quality of their ore, which was 59 percent in 1963. New beneficiation plants at the mines of the two producers, completed in 1962, entered normal operations in 1963. Exports in 1963 totaled 808,879 metric tons; major destinations were United Kingdom, 226,645; Czechoslovakia, 205,362; West Germany, 163,494; and France, 97,438.

Investigations of the Khenifra and other deposits were continued in 1963 by the Directorate of Mines and Geology and two companies, but on a reduced scale. The project for the establishment of a steel plant at Nador remained under active consideration during 1963, but no decision was announced.

Lead and Zinc.—Moroccan lead production was adversely affected by the labor unrest in early 1963 and general market conditions. This was reflected in the decreased exports of lead concentrate and in the decreased amount of lead metal produced at the Ouad-el-Haimer

Digitized by Google

35,000-metric-ton-per-year smelter of Fonderies Penarroys-Zellidja. The 1963 output of lead concentrate (average grade 68 percent), local sales to the smelter, and exports through November are presented in table 4.

TABLE 4.—Production in 1963, and local sales to smelter, and exports of lead concentrates through November

(Metric tons)

Company and mine	Production	Local sales	Exports
Société des Mines de Zellidja, Boubeker	19,400	19,068	
Compagnie Royale Asturienne des Mines, Hassi Touissit	18,810	3,121	17,484
Société des Mines d'Aouli, Aouli and Mibladen	35,000		33,319
Société Penarroya-Maroc, Ksar Moghal	5,130	1,729	2,116
Société Minière de Jebel Aouam, Jebel Aouam	12,600		12,057
CADET (Cooperative), Tafilalet area	4,700		4,490
Société Minière de l'Atlas, Keba	10,430		1,420
Compagnie Minière d'Agadir, Merouane			1,300
Various other companies		217	6,416
Total	106,070	24,135	78,602
Total 1963 local sales and exports		27,383	83,196

Major export destinations in 1963 were France, 70,301 metric tons; Italy, 7,051; and West Germany, 2,981. Additional quantities of lead concentrate were supplied to the smelter by Zellidja's Algerian affiliate, Société Nord- Africaine du Plomb, whose workings are contiguous to the Boubeker mine. Exports of smelter product were to France (16,722 metric tons), Algeria (420 tons), and Czechoslovakia (270 tons); the total was 17,598 tons. Local sales amounted to 938 tons.

Total production of zinc concentrate in 1963 was 58,618 metric tons (58,810 tons in 1962). Metal content, however, rose from 34,420 tons to 37,582 tons as the result of increase in average grade from 58.49 to 64.11 percent; the higher tonnage and grade from the Hassi Touissit mine accounted for the overall increase in contained metal. Zellidja's Boubeker mine was the principal producer with 33,294 metric tons, followed by the Hassi Touissit with 20,460 tons and three other small producers with a total of 4,864 tons. Corresponding figures for exports were 33, 880, 19,390, and 4,629 tons, respectively. Of the 57,899 tons exported, France was consigned 45,723 tons; Poland, 6,626 tons; and Belgium, 1,882 tons.

Manganese.—The sharp decline in manganese ore production and exports was due mainly to the suspension of purchases for the U.S. stockpile, effective at the beginning of the year, and competition from the New Gabon production. Production in 1963 was 68,900 metric tons of chemical ore (100.599 in 1962) and 266,050 tons of metallurgical ore (368,758 in 1962). Exports totaled only 308,310 metric tons, consisting of 68,652 tons of chemical ore, 154,108 tons of metallurgical ore, and 85,550 tons of sinter. Mine stocks dropped during the year from 171,743 tons to 136,416 tons. The Imini mine of Société Cherifienne d'Études Minières maintained its position as principal producer with an output of 63,604 metric tons of chemical ore and 119,190 tons of metallurgical ore. Société de Bou Arfa produced 109,735 tons of metallurgical ore from its mine of the same name. Output by Compagnie di Tifnout-Tiranimine consisted of 5,355 tons of metallurgical

Digitized by Google

ore. The remaining 31,786 tons of metallurgical ore and 5,293 tons of chemical ore came from at least nine other producers; 2,868 tons of the chemical ore came from deposits worked by the miners' cooperative in the Ouarzazate area. Average grade of metallurgical ore mined through October was 41.0 percent manganese (42.3 percent in 1962); that of the chemical ore was 81.5 percent manganese dioxide (80.0 percent in 1962). Sinter production was 86,400 metric tons at Sidi Marouf and 2,670 tons at Bou Arfa; quantities of ore sintered were 108,690 and 4,072 tons, respectively.

NONMETALS

Barite.—Production of barite in 1963 established a new high and maintained the almost continual growth since 1959. Exports were 94,713 metric tons, 41 percent above the 1962 total; 52,108 tons were consigned to the United States. Shipments were made to Italy and Venezuela, countries which did not take any exports in 1962, indicating a wider market acceptance of Moroccan barite. Local sales were 1,330 metric tons; these and exports totaled 96,043 tons, of which 81,496 tons came from the Jebel Irhoud mine and 14,547 tons from the Tessaout mines of Compagnie Marocaine des Barytes, a BRPM affiliate. Because exports and local sales exceeded production, old stocks were depleted by 1,489 tons.

Fluorspar.—The greatly expanded fluorspar production in 1963 came from a deposit near Meknes, opened up by Société Anonyme des Entreprises Minières, a company owned by the Continental Ore Corp. of New York and BRPM. The production was stocked until December when the first shipment was made.

Phosphate Rock.—The 5-percent increase in phosphate rock output in 1963 established a record high. Production came from OCP's two groups of mines, both exploited by opencut and underground methods, at Khouribga (about 100 kilometers southeast of Casablanca) and Youssoufia (about 60 kilometers east of Safi). The Khouribga mines produced 6,115,247 metric tons and the Youssoufia mines, 2,433,167 tons, increases of 4 percent and 7 percent, respectively. Exports and local sales (in metric tons) follow:

	Exports	*Local sales*	*Total*
Khouribga	5,929,191	64,352	5,993,543
Youssoufia	2,523,694	7,785	2,531,479
Total	8,452,885	72,137	8,525,022

Exports to major destination follow:

	Metric tons
France	1,417,143
Belgium	920,071
United Kingdom	802,901
West Germany	736,662
Spain	715,585
Netherlands	403,003

OCP announced plans for opening up a deposit at Meraa-el-Arech, 20 kilometers from Khouribga; expectations were that production would start early in 1965 at a daily rate of 6,500 tons. Efforts to improve mining techniques through the use of larger open-pit equipment and more efficient underground methods continued. The ultramodern

Digitized by Google

washing plant at Oued-Zem reportedly produced high-quality phosphates, comparable to those of Senegal and Togo, contributing to the Khouribga output. Pilot plant studies on the beneficiation of low-grade rock continued. Efforts made to expand markets included visits of OCP technical representatives to consumers' plants in Europe and Asia to assist in improving the final product.

Potash.—During 1963 Société des Potasses des Zemmours, in which BRPM holds a 50-percent interest, intensified exploration of the Triassic potash deposits in the Khemisset, Berrechid, and Safi regions. Indications are that the Berrechid offers some promise because of its proximity to Casablanca (40 kilometers south), but the economic possibilities are not completely proved. The Safi deposits are obviously small but could be utilized in the chemical complex being installed at Safi. The National Institute of Agricultural Research carried out a specialized investigation of the use of potassium fertilizers on Moroccan soils.

MINERAL FUELS

Coal.—Despite the increased production of anthracite from the Djerada colliery of Charbonnages Nord-Africains, 49 percent owned by BRPM, the output was still below the 1959–61 level. The increase was partly the result of a larger domestic demand, with local sales at 206,250 metric tons (201,506 in 1962). Exports were 172,456 tons (159,920 in 1962). Major destinations were France (49 percent), Belgium (16 percent), and Algeria (14 percent). Production per man-shift underground averaged 692 kilograms through November (636 in 1962). Coal imports through October were at the annual rate of 111,300 metric tons (70,529 tons in 1962). Total consumption for the 10-month period was at the annual rate of 289,000 metric tons (271,000 in 1962). Consumption by major sectors was power generation, 47,300 metric tons; phosphate industry, 26,300; cement plants, 108,000; and sugar refineries, 13,700.

In an attempt to improve efficiency and costs at Djerada, BRPM signed an agreement in September with the West German firm of Preussische Bergwerks und Hütter Aktiengesellschaft (PREUSSAG) to extend technical assistance over a 15-month period.

Petroleum.—The record high for production established in 1963 was due to the increased output from the Sini Rhalem field near Essaouira, which was discovered in late 1961. The older fields in the Sidi Kacem (Gharb) area, nearly exhausted, contributed only 35 percent of the total. All production was by Société Cherifienne des Pétroles (SCP), in which BRPM has a 49.9 percent participation.

The petroleum refinery of SCP at Sidi Kacem and that of Société Marocaine Italienne de Raffinage, jointly owned by the Italian group Ente Nazionale Idrocarburi (ENI) and BEPI, handled the increased production of crude and the 878,739 metric tons of supplementary imports. The latter facility, situated at Mohammedia, entered service in April 1962. With the increased availability of domestic crude and the increased total annual refinery capacity to 1.5 million metric tons, imports of refined products were correspondingly lower than in 1962. Combined imports of gasoline, kerosine, and fuel oils through October were at the annual rate of 4,512 metric tons (28,400 tons in 1962).

Digitized by Google

Local sales of refined products, roughly equivalent to consumption, follows:

Premium gasoline	barrels	739,335
Regular gasoline	do	1,424,376
Kerosine	do	473,521
Diesel oil	do	1,878,914
Fuel oil	metric tons	292,685
Butane gas	do	24,827
Propane gas	do	2,659

Oil prospecting in various parts of Morocco continued without notable success. SCP endeavored to increase reserves in the areas being exploited. Société Marocaine Italienne des Pétroles, an association of ENI and BRPM, was active in the Tarfaya region and in March was authorized to explore an area of 12,000 square kilometers south of Oujda on the Algerian border. Compagnie Financière de Pétroles, a Belgian concern, in cooperation with BRPM, explored in the Draa Valley. PREUSSAG began work in the Doukkala plain, between Safi and El Jadida. In September an agreement was reached to admit the Richfield Oil Co. to the concession held by a North American group, Allen & Co., Inc., of New York, and Canadian-Delhi Oil, Ltd., which had begun exploration in the Boumalne-Boudenit-Tafilalet region near the Algerian border.

At the end of 1963 the labor force engaged in petroleum production totaled 718. In October an agreement was reached between officials of UMT and the retail motor fuels dealers association setting up a nationwide collective labor agreement. To make possible the benefits of the agreement, a decree was issued at the end of the year reducing wholesale prices for gasoline and high-test gasoline by DH0.014 per liter (about 1.5 cents per gallon). The retail prices were to remain the same and the profit margin would allow the implementation of the agreement. The profit which the Government receives annually because of its effective monopoly of oil importing and refining will be diminished substantially.

The Mineral Industry of Mozambique

By Thomas G. Murdock[1]

THE MINERAL extractive industry in the Portuguese oversea Province of Mozambique showed little significant change in 1963. Mineral production was chiefly by the same individuals or collective enterprises as in the past. On the basis of value, Mozambique's contribution to world mineral supply has been negligible, however, its unusual pegmatite mineralization has gained a certain renown. In 1959 the country ranked third in world production of beryl with 14 percent of the total, but declining prices and mining difficulties intervened, and in 1962 it occupied sixth place with only 6 percent. In 1962 Mozambique was the world's fifth-ranked producer of columbium-tantalum concentrates with about 3 percent of the world total.

In 1963 new plants were inaugurated for cement manufacture and processing montmorillonite. Mozambique continued to play an important role in the transportation of minerals, metals, and fuels of other countries. An appreciable part of the trade of the Republic of South Africa, the Federation of Rhodesia and Nyasaland, and the Republic of the Congo (Léopoldville) moved through the ports of Lourenço Marques and Beira. During 1963 construction was in progress on additional facilities for this transit trade, including a pipeline into Southern Rhodesia, a railway connection for the evacuation of Swaziland iron ore, and a mechanical ore-loading dock at Lourenço Marques.

The 1962 mine production was valued at Esc80 million (US$2.8 million),[2] of which coal accounted for 43 percent. Adding in the value of cement and lime (Esc124 million) and other quarry products (Esc36 million), all estimated on the basis of official 1961 production statistics, the total was Esc240 million. For 1958 the gross domestic product (GDP) has been reported at approximately Esc12,004 million. If the 1962 GDP was 29 percent above that of 1958, as were all exports, the total contribution to the 1962 GDP by the mining and quarrying industry would have been 1.6 percent. The 1962 value of products from the refining of imported crude petroleum was Esc304 million, 24 percent of that of all industrial production.

Employment by the mining and quarrying industries, including cement and lime plants, on January 1, 1962, totaled 334 administrative, technical, and office personnel, and 9,752 workmen; the latter comprised 11 percent of the total industrial labor force. Total salaries and wages for both categories of employees was Esc60 million in 1961, or 9 percent of the total industrial labor bill. An additional 305 employees of all categories were engaged in petroleum refining, and their 1961 total earnings were Esc17 million.

[1] Mining engineer, Division of International Activities.
[2] The basic unit of currency is the escudo (Esc). At par value US$1=Esc28.58 (Esc1=US$0.03499).

GOVERNMENT POLICIES AND PROGRAMS

No significant mining legislation was enacted during 1963. Basic mineral legislation applicable to Mozambique was published in book form in English by the Mozambique Government Press, Lourenço Marques. The mining laws of Mozambique follow the premise that the subsoil is the property of the State. Prospecting on private land is permitted by law; compensation for mining operations on private land is made by private agreement or by arbitration by the courts. Prospecting on government land (most of Mozambique) is free, but the Government may reserve certain areas and forbid prospecting in them. At the end of 1963 several areas were closed, but indications were that all mineral resources in the country might be opened to prospecting.

Despite a continuation of the Government's Development Mission of the Zembézi invitation to develop fluorspar deposits in the Macossa-Marinque region, coppier and iron in an area north of Tete, and cassiterite deposits at Inchope, no public announcements of tender awards were made. Several concessions for pegmatite economic minerals were granted; however, the total area of these was 1,550 hectares. At the beginning of the year, 76 concessions, exclusive of rights for oil exploration, were in effect, covering 12 million hectares, of which 6 million were in Tete District and 4 million in Zambézia.

Efforts to eliminate gradually customs duties on Mozambique trade with Metropolitan Portugal and other escudo areas were continued in 1963. Imports from the dollar area were restricted to commodities considered essential for the local economy and not readily available from Portugal and its overseas provinces or from European Common Market countries. In July the foreign currency reserve of the Mozambique Exchange Fund were completely exhausted, for the first time since establishment of the Exchange Fund in 1932. The Exchange Fund has been maintained through the obligation of exporters to surrender 95 percent of their export earnings to the Fund. After July, payments by the Fund were restricted severely and usually limited to the level of monthly earnings and occasionally payments had to be made from the fast-ebbing gold reserve.

To the extent that available funds permitted, the Government continued its program of economic development. This program, as in previous years, emphasized the improvement and expansion of transportation and communication facilities; expectations were that expenditures of Esc22 million would be made during the year.

In January the President of the Foreign Commerce Board of Mozambique announced a new government attitude toward foreign investment, although this has not been confirmed by any Portuguese Government document. According to the unofficial statement, it will no longer be necessary for firms in Mozambique to have a majority of Portuguese-held capital or administrative control. Other modifications reportedly include a special tax moratorium for new industry, a guarantee covering the repatriation of profits, most favored transportation rates, and possibly exclusive manufacturing rights for periods up to 10 years.

Digitized by Google

SOURCE MATERIAL

In general information about the mineral industry of Mozambique is adequate and reliable; it is mainly from the Foreign Service dispatches of the U.S. Consulate General at Lourenço Marques, and those prepared by the Regional Minerals Officer on duty at the U.S. Consulate General, Johannesburg. These are supplemented by several publications of the Portuguese Government and technical journals. The 1961 industrial statistics volume of the Mozambique Directorate of Economy and General Statistics was a principal source, giving much detailed information of the extractive and related industries.

PRODUCTION

The 1963 output of most minerals was well below the average of preceding years, and in very few cases was it above that of 1959. Refined petroleum products are the exception; output of these set a record in 1963.

Data on production of the quarry industry are available only for 1961. The 1963 production was probably approximately the same, or slightly lower. In 1961 output was as follows: Clay (other than kaolin and montmorillonite) 129,000 tons; granite 730,000 tons; limestone 434,000 tons; rhyolite 62,600 tons; and sand and gravel 130,000 tons.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:					
Bauxite	4,284	4,840	4,671	6,216	6,597
Beryl, 11 to 12 percent beryllium oxide (BeO)	1,414	1,496	973	569	556

TRADE

Complete data on minerals and metals trade are not available for any year since 1961, when imports of these commodities were valued at Esc681 million (Esc484 million in 1960); exports were valued at Esc259 (Esc63 million in 1960).[3] The appreciable increases in 1961 were mainly due to the Mozambique refinery which began full-scale operations in early 1961; crude petroleum was imported for the refinery, and exports of refined products began. The value of 1962 imports is estimated at Esc602 million and of exports at Esc299 million. Through October 1963, imports were at the estimated annual rate of Esc576 million and exports at the rate of Esc288 million.[4] Decreased imports and increased exports of refined petroleum products accounted for most of the 1962 decline in total imports and increase in total exports. Greater utilization of domestically refined products permitted a further decrease in 1963 imports; total exports were adversely affected by the reduced shipments of metallic ores and thus were slightly below those of 1962.

In 1961 minerals and metals accounted for 17 percent of all imports and 9 percent of all exports. Of the imports in that year, fuels totaled Esc440 million, metals Esc218 million, and nonmetals Esc23 million. Of the exports, fuels were valued at Esc195 million, metals Esc62 million, and nonmetals Esc2 million.

Mozambique's minerals and metals trade shows substantial diversification; there were 36 suppliers and 22 recipients in 1961, exclusive of bunkers and including Portugal's other oversea provinces. In that year Iraq was the chief supplier with 37 percent of the total; other major suppliers were the Republic of South Africa with 16 percent, the European Economic Community countries whose combined total was also 16 percent, and Iran with 9 percent. Portugal supplied only 3 percent. Receipts from the United States amounted to Esc16 million, 2 percent of the total, and consisted of fuels valued at Esc11 million and metals valued at Esc5 million. These constituted 6 percent of all imports from the United States.

The Republic of South Africa was the principal destination of 1961 mineral exports, with 30 percent of the total, followed by the United States (16 percent), bunkers (15 percent), French Somaliland (15 percent), and the Federation of Rhodesia and Nyasaland (9 percent). Exports to the United States were valued at Esc42 million; consisted almost exclusively of metallic ores and constituted 28 percent of the total exports to the United States.

In 1961 the ports of Beira and Lourenço Marques handled direct transit shipments of minerals, metals, and fuels to and from the Federation of Rhodesia and Nyasaland, the Republic of South Africa, and the Republic of the Congo (Léopoldville) amounting to 2,358,000 tons valued at Esc10,036 million. These totals include a small quan-

[3] The 1960–61 exports are exclusive of maritime and aviation bunker deliveries made from stocks of petroleum products in transit. All bunker sales were made from stocks in 1960 and were valued at Esc67 million (Esc64 million maritime and Esc3 million aviation); for 1961 they were reported at Esc62 million (Esc57 million maritime and Esc5 million aviation), and in addition fuels from the local refinery valued at Esc40 million were considered as exports.

[4] For 1962 and 10 months of 1963 values are available only for all common metals and manufactures combined. The estimates assume that the proportion of scrap, crude, and semimanufactures in the total was the same as in 1961.

Digitized by Google

tity of transshipments to other destinations. Copper was the principal commodity handled on the basis of value (364,953 tons and Esc6,315 million); gasoline led on the basis of quantity (662,573 tons and Esc748 million). Minerals, metals, and fuels comprised 66 percent of all direct transit shipments on the basis of volume and 47 percent on basis of value.

TABLE 2.—Exports of major metals and minerals

(Metric tons unless otherwise specified)

Commodity	1960	1961	Principal destinations, 1961
Metals:			
Aluminum	(1)	22	All to Republic of South Africa.
Copper	239	347	Japan 122, West Germany 106, Republic of South Africa 66.
Iron and steel:			
Ferrous scrap	10,107	7,729	Japan 7,707, Netherlands 15.
Rolled products	14	73	Republic of South Africa 63, Federation of Rhodesia and Nyasaland 8, Angola 2.
Lead	122	214	Republic of South Africa 206.
Tin, long tons	(1)	1	All to Republic of South Africa.
Zinc	(1)	8	Do.
Other metals, unspecified	234	3	All to Portugal.
Ores, metallic, unspecified [2]	9,555	5,838	Federation of Rhodesia and Nyasaland 4,147, United States 1,093. [3]
Nonmetals:			
Asbestos	80	159	United Kingdom 138, United States 21.
Diatomite	13	39	All to Republic of South Africa.
Lime		33	All to Federation of Rhodesia and Nyasaland.
Mica	1	2	United States 1.
Salt	4,855	4,145	Federation of Rhodesia and Nyasaland 4,128.
Other, unspecified	241	181	Belgium-Luxembourg 100, Netherlands 54, Republic of South Africa 18.
Mineral fuels:			
Coal	59,539	60,826	Federation of Rhodesia and Nyasaland 60,700, bunkers 56.
Petroleum products: [4]			
Gasoline		47,767	Republic of South Africa 42,004, Federation of Rhodesia and Nyasaland 5,763.
Kerosine	1	1	All to bunkers.
Distillate fuel oil	50	52,114	Republic of South Africa 32,402, bunkers 8,948, French Somaliland 6,488.
Residual fuel oil		190,513	Bunkers 65,801, French Somaliland 79,846, French West Africa 14,870, Iraq 11,391.
Lubricants	32	21	All to bunkers.
Other		18	All to Republic of South Africa.
Total	83	290,434	French Somaliland 86,334, bunkers 74,837, Republic of South Africa 74,692, French West Africa 14,870.

[1] Included with other metals.
[2] In 1960 exports consisted of 4,459 tons of bauxite, 5 tons of cassiterite concentrates, 3 tons of iron ore, 5,054 tons of unspecified ores, and 34 tons of miscellaneous mineral raw materials. The unspecified ores include beryl, columbite, ilmenite, and tantalite. The 1961 data make no itemization of what is included, except for 5 tons of iron ore shipped to Japan.
[3] U.S. imports were beryl, 992 tons; columbite concentrate, 27,494 kilograms; and tantalite concentrate, 99,722 kilograms.
[4] Following the completion of the Mozambique refinery (to use imported crude) in late 1960, part of the maritime bunker deliveries are shown as exports. In 1960 these deliveries were made from transit stocks and amounted to 109,815 tons; in 1961 transit stocks supplied 97,082 tons in addition to quantities shown as exports. Aviation bunker deliveries are also supplied from transit stocks and were 2,099 tons in 1960 and 3,099 tons in 1961.

COMMODITY REVIEW

METALS

Bauxite.—Mining of bauxite at the Alumen and Alumen West mines of Companhia de Cimentos de Moçambique, in Mozambique, about 8 kilometers northeast of Penhalonga, Southern Rhodesia, continued at approximately the rate of the immediately preceding years. Part of the production (5,511 tons in 1962) was exported to Southern Rhodesia and the Republic of South Africa for use in manufacturing alum for water treatment. About 10 percent of the exports are of nodular gibbsite used in manufacturing alumina refractory bricks in a plant near Johannesburg. The bauxite produced averages about 60 percent alumina and 10 to 20 percent silica.

Beryl.—Low prices for beryl did not permit an expansion of beryl production, which remained well below the 1960 high. On a basis of tonnage, however, beryl assaying 11 to 12 percent beryllium oxide (BeO) was the principal mineral produced from the numerous complexly mineralized pegmatites of the Alto Ligonha and adjacent areas of Zambézia District. The total production value for all pegmatite minerals was about Esc46 million in 1961.

The principal 1963 producer of beryl was Empresa Mineira do Alto Ligonha (EMDAL) with 181 tons (320 tons in 1961) from its mines around Muiane. The Napido mines of Monteminas, Ltd., and those of an associated company, Sociedade Mineira de Melela, Ltd., were idle during 1963; in 1961 they produced a total of 483 tons. The Muneia mine of Sociedade Mineira de Mutala, Ltd., produced 40 tons (70 tons in 1961). Other producers were Sociedade Mineira da Zambézia, Ltd., (50 tons in 1961), Minas de Mocuba, Ltd., and Sociedade Mineira de Mocuba, Ltd.

As elsewhere, the beryl ore occurs in greatest concentration between the quartz core of the pegmatite and the kaolinized feldspar normally surrounding it. Most mining is by the opencut, primitive methods

Digitized by Google

that characterize pegmatite mining throughout the world; the recoverable beryl is hand-cobbed. With the sparse mineralization in beryl, the recovery of other minerals (including bismuth, cassiterite, columbite-tantalite, euxenite, lepidolite, muscovite mica, microlite, monazite, pollucite, and tourmaline), when present in economic quantities, is necessary for a profitable operation. Only the richest of the scores of pegmatites known are exploited. Part of the production results from exploration.

Despite poor demand for beryl, interest of individuals and firms in registering claims for mining concessions continued, and in 1963 several were granted covering beryl and associated minerals. Seven claims, totaling 1,352 hectares, were granted to EMDAL.

Columbium-Tantalum.—The 1963 production of columbium-tantalum minerals dropped somewhat from that in 1962 because of low market prices. Although these minerals are often a byproduct or coproduct of mining pegmatites for beryl, the only major producer, Sociedade Mineira de Marropino, Ltd., emphasizes recovery of columbite-tantalite and microlite. In 1961 this company produced 92 tons of the former and 31 tons of the latter; in 1963 the output was about 57 tons and 73 tons, respectively. Marropino exploits the Morrua deposit west of the Melela River and opposite Napido, where a large flat-lying pegmatite is mined both by hand labor and mechanically. Stripping is done with a bulldozer, front-end loader, and trucks. The ore is treated in a washing plant of perhaps 500 tons of feed per day, where it undergoes screening, followed by gravity concentration and magnetic separation. The product assays 57 to 64 percent tantalum pentoxide and 18 to 24 percent columbium pentoxide. EMDAL is the second largest producer of the pentoxide minerals and small quantities were recovered by the several other beryl producers.

In an endeavor to improve recovery, the operators have modified the plant procedures. The Marropino plant was estimated to be recovering not over 35 percent of the fine tantalite and microlite; additional tables have been installed and another rodmill is to be added. The Mutala Co. formerly recovered tantalite-columbite chiefly in sluices, but in 1963 installed a jig and a shaking table, and ordered another table and a rodmill. In spite of an overall decline in production, their recovery rose considerably, and for the first time a small quantity (1.3 tons) of microlite was recovered in the second half of 1963.

Copper.—The Edmundian Investments Co., a South African concern, reopened a mine in the Isitaca mountains near Manica which had been idle since 1922. The ore was reported to contain 7.5 percent copper. Production at the rate of 1,000 tons of concentrate per month [5] was expected.

NONMETALS

Cement.—In November, Companhia de Cimentos de Moçambique inaugurated the province's third cement plant at Nacala in northern Mozambique. Annual capacity is 100,000 tons; with the Lourenço Marques (131,000 tons) and Beira (100,000 tons) plants of the same company, total capacity is 331,000 tons. The new plant reportedly cost Esc150 million, and the total cost of the three was Esc500 million.

[5] Mines et Metallurgie (Paris). No. 3581, February 1964, p. 62.

Digitized by Google

The Najala plant is designed to meet the requirements of the Districts of Moçambique, Cabo Delgado, and Niassa; saving on transportation charges may permit sales at lower than previously priced. Expectations are that the new unit will operate at only 20 percent capacity until consumption increases. The decline in production since 1960 has been due to reduced construction activity following the completion of several large public works projects. With the additional capacity now available the announced planned expansion of the Lourenço Marques plant by 200,000 tons annually has not yet been started.

Lithium Minerals.[6]—In the early 1950's the production of lepidolite was of some significance, reaching a peak of 5,712 tons in 1953; however, during recent years it has been small, intermittent, and limited to the byproduct recovery by EMDAL. In late 1963, Marropino started the recovery of lepidolite in the face of a modest demand, but the price was low.

Montmorillonite.—The small production of montmorillonite reported since 1959 has been exported in crude form, mainly to the Republic of South Africa. On October 23, 1963, a plant for processing the crude into a product known as "coral bentonite" was inaugurated near Impamputo, about 56 kilometers from Lourenço Marques. The plant, adjacent to the deposit exploited by open-pit workings employing 60 to 80 laborers, is owned and operated by Lucinada Umbeluzi Mine, Limitada, a Mozambique firm which has invested Esc5 million in the first phase of its operations. Plant capacity is 25 tons daily; production costs are reported at Esc480 per ton, and the selling price on delivery in railway cars at Boane station at Esc720 per ton.

Perlite.[7]—In May 1963, an exclusive charter for perlite exploration was granted to Bedaux, Limitada, a French firm in Lourenço Marques. The concession area is in the District of Lourenço Marques, directly west of Boane. The charter, granted for 2 years, is renewable for 1 year. Renewal of the concession requires the expenditure of at least Esc1 million per year in the form of salaries, wages, and other expenses in Mozambique and Portugal.

MINERAL FUELS

Coal.—Coal continued to be the most valuable mineral product of the country. All production came from a mine at Moatize, 16 kilometers northeast of Tete, where Companhia Carbonifera de Mozambique, of Portuguese-Belgian ownership, exploited deposits in its concession area, which contains about 20 million tons above the 300-meter level. The coal produced contains about 21 percent volatile matter and 19 percent ash. About 45 percent of production is fines smaller than 6 millimeters, and only about 40 percent of the fine coal can be sold. The production continued to be consumed largely in Mozambique by the railroads, the cement plant at Beira, power stations, and small industrial enterprises. Exports dropped to 51,935 tons in 1962 and are believed to have been about the same in 1963. The chief

[6] Minerals Yearbook, v. 1, 1962, p. 821, indicates that in 1962 U.S. imports from Mozambique amounted to 5,661 short tons. This is due to an erroneous declaration of origin for these imports which came from Southern Rhodesia via Mozambique.
[7] Canadian Mining Journal (Quebec). V. 85, No. 2, February 1964, p. 164.

Digitized by Google

export market has been Nyasaland, where the coal was used for the same purposes as in Mozambique. Pithead price of the Mozambique coal has been about Esc100 per ton, compared with Esc80 for Southern Rhodesian coal and Esc50 for South African coal. Thus the Moatize coal can only be marketed within the limited radius where transportation advantages favor it. The domestic production does not meet the country's coal requirements and the deficit has continued to be met by imports from the Republic of South Africa and the Wankie Colliery in Southern Rhodesia. Despite some replacement of coal by fuel oil since the inauguration of the Mozambique refinery, coal imports increased in 1962 to 324,007 tons; however, through September 1963 they dropped to an annual rate of 304,660 tons, roughly that of 1961.

Petroleum.—Mozambique Gulf Oil Co., owned equally by Gulf Oil Corp. and Pan American Oil Corp., has carried out extensive but unsuccessful exploration since 1948. Of the 11 holes drilled, all but 3 were dry and these gave gas in quantities which the company considered uneconomic. Another group is conducting a market survey in Mozambique and adjacent countries for possible piping from the Buzi No. 1 well south of Beira, where an Upper Cretaceous sand below 1,430 meters yielded a small flow and was capped. Exploration was continued on a reduced scale in 1963 and included the drilling of Pande 2 as an attempted stepout from the 1961 gas discovery there. At yearend, geological exploration in the Zambézi Delta area was underway, and preparations were being made for offshore exploration. In 1962 it was reported that Gulf's current annual expenditures were about Esc28 million.

The refinery at Matola, a suburb of Lourenço Marques has a reported annual capacity of 600,000 tons. It was operated by Sociedade Nacionale de Refinacão de Petroleos (SONAREP), an affiliate of a Portuguese oil company, and partly owned also by private individuals and firms in Mozambique. Output of refined products from imported crude increased by 5 percent in 1963, and butane gas was produced for the first time. Imports of crude totaled 436,820 tons (399,053 tons in 1962). Exports through September 1963, including domestically refined products delivered to maritime bunkers, were at the annual rate of 420,000 tons (269,650 tons in 1962). Increased exports in 1963 were partly due to fuel oil shipments to Portugal, amounting to 67,000 tons through November. Fuel oil shortages were reported in November for the central and northern regions of Mozambique, chiefly for lack of shipping facilities. The exports to Portugal were believed to have been a move to conserve Portuguese escudos within the Portuguese economic area, to strengthen the exchange position of Mozambique in metropolitan escudos, or to find an outlet for surplus production to replace the originally expected markets in earby African territories, which apparently failed to materialize.

Late in the year SONAREP reported plans to invest an additional Esc87 million in the expansion of refinery facilities to provide an annual asphalt production capacity of 118,000 tons and one of 25,000 tons for butane gas. At the beginning of 1963, it was announced that SONAREP had formed a subsidiary company in the Republic of South Africa, known as SONAREP (South Africa), Pty. Ltd., with

Digitized by Google

a paid-in capital of 20,000 rands (US$28,000) for the purpose of distributing its refined products throughout that country.

Early in the year Portuguese newspapers expressed concern with the announcement of plans for the construction of a pipeline from Durban to Johannesburg. The installation of this facility will be serious for Mozambique since petroleum products now unloaded and transported by rail from Lourenço Marques to the Transvaal represent about 75 percent of all freight between the two points and about 25 percent of all port and rail traffic; the Republic of South Africa also has been an important recipient to products from the Mozambique refinery.

Preliminary work under the supervision of a U.S. contractor was completed on the 25-centimeter crude oil pipeline to connect Beira with the Southern Rhodesian refinery being built at Feruka, 18 kilometers from the Mozambique border. By the end of 1963, almost 158 of the 340 kilometers of the pipeline were laid. The Beira Railway is expected to get annual compensation of about Esc12.5 million for the transportation of crude oil by pipeline. A local hydroelectric company will supply the power for the 1,000-horsepower pumping stations to be located at Beira and at Maforga.

Consumption of petroleum products in 1963 is believed to have been slightly above the 1962 level; in 1962 the following quantities were used:

Gasoline	1,000 liters	58,097
Kerosine	do	23,718
Fuel oils	metric tons	99,008
Lubricants	do	7,323

The Mineral Industry of Nigeria

By Taber de Polo[1]

UNTIL the advent of commercial production of petroleum in 1958, tin was the backbone of Nigeria's mineral economy. Since that year, petroleum has become the first-ranking mineral product, and tin second.

Mineral production has contributed substantially to Nigeria's national economy as reflected in its share of the value of exports, and of industrial employment. In 1962, the latest year for which complete trade data are available, petroleum accounted for 10.2 percent of the value of all exports; tin accounted for 4.3 percent; and columbite, coal and others for another 1 percent. Directly and indirectly the minerals industry furnished employment for 100,000 Nigerians.

Proven petroleum reserves in Nigeria are sufficient to provide for a substantial increase in foreign exchange earnings each year for a number of years. It is likely that reserve figures will continue to increase in view of extensive exploration, both on land and offshore. Reserves of natural gas are also substantial.

In 1963, Nigeria supplied about 4.6 percent of the estimated world tin production and 6.1 percent of free world production of this commodity. The proven reserve of tin ore is estimated at 136,000 tons, and this position reportedly has not changed materially from year to year because the cassiterite produced every year has been partly obtained from outside the declared reserve and because new prospecting has replaced that obtained from declared reserves. Nigeria ranked first among free world producers of columbite and tantalite in 1963, supplying 50.3 percent of recorded new production. The proven reserve of columbite produced mostly as a byproduct of tin, is given as 67,000 tons, and there are large deposits not yet exploited.[2]

Nigeria has reserves of iron ore, coal, and limestone which may be used in a proposed primary steel industry. Coal and limestone mining were already substantial industries in 1963, but no iron ore had been mined commercially by yearend.

The estimated value of reported mineral production in 1962 amounted to almost N£27 million[3] (US$75.6 million). This figure does not include the value of limestone for cement; sand, crushed stone and gravel for mixed concrete, and clays for drilling mud, brick, and pottery. Government revenue from mining and petroleum production operations totaled N£9.9 million, of which oil industry payments totaled over N£8.5 million.

[3] The monetary unit of Nigeria is the Nigerian pound (N£); N£1=US$2.80.

Digitized by Google

The mining industry was largely in British hands; the oil industry was controlled by British, Dutch, and United States firms. From October 1, 1960, to October 1, 1963, the number of U.S. firms represented in Nigeria increased from 14 to 67; the more recent figure included 6 firms engaged in petroleum exploration and marketing and 3 firms engaged in mining and other industry.[4]

The first 6-year national development plan (1962–68) called for a total expenditure of N£676.5 million. Under the plan, progress has been made on a number of projects affecting the minerals industry, including Shell Oil's N£10 million refinery. Discussions and planning continued for the installation of the integrated iron and steel industry.

A number of mineral and metal processing and consuming facilities were completed or under construction during 1963; an aluminum rolling mill, a plant producing industrial gases, a galvanized sheet plant, and a glass factory, all at Port Harcourt; a metal container plant at Apapa; a 50,000-ton capacity clinker-grinding plant for cement at Yioko; brick plants at Ikeja and Lagos; a steel rolling mill; an asbestos cement products plant; and an enamelware plant.

Progress was made during the year on commitments to finance the Niger Dam, and tenders were publicly opened for the civil works part of the project. The lowest bid was for N£35.7 million, from an Italian firm. Contracts were signed for preliminary work (roads and access bridges) for the project. A power shortage hindered the development of industry; but progress was made on improvements. During 1963 the Afam power station using natural gas was completed and started operating in May. A N£3.8 million contract was awarded for a new Delta power station at Vyhalli to use natural gas to supply electricity to the Lagos-Ibadan area.

GOVERNMENT POLICIES AND PROGRAMS

In 1963, the Government continued its policy of promoting foreign investment. In the Annual Report of the Mines Division of the Ministry of Mines and Power for the year ended March 31, 1962, The Minister of Mines and Power (as of April 17, 1963) expressed his gratification for "the confidence which overseas investors have shown in Nigeria" and further stated that "history will prove that this confidence is not misplaced."

The Government policy of qualifying Nigerians for technical, supervisory, and administrative positions was also continued. As of March 31, 1962, 21 Nigerians occupied senior staff positions in the Division of Mines, Ministry of Mines and Power, and 12 Nigerians were in training for such positions. Mineral industry companies assisted along these lines; their activities in this field included on the job training programs as well as financing technical education of Nigerians overseas.

Industrial feasibility surveys were sponsored and were generally conducted by experts supplied by American, British, United Nations, and other technical assistance programs.

Changes in Government revenue levels on several commodities influenced the mineral industry. Customs' tariff order Legal Notice No. 42 of 1963 exempted fluorspar and ferroalloys of manganese and

[4] U.S. Embassy, Lagos, Nigeria. State Department Dispatch No. A–299, Nov. 16, 1963, p. 13.

Digitized by Google

silicon from import duty and removed the export duty on tin and tin ore. Legal Notice No. 82 of 1963 removed export duty of N£1 (US$2.80) per ton on columbite. Legal Notice No. 72 of 1963 accorded pioneer status to the smelting and refining of base metals and the manufacture of their alloys. Pioneer industry status gives a company advantages of income tax relief. The royalty on coal mined by the Nigerian Coal Corp. was abolished on February 1, 1963. A number of tariff increases at the end of the year illustrated the Government's determination to protect local industry.

The Minister of Mines and Power announced in April that Nigeria has applied for membership in the International Atomic Energy Agency. A comprehensive petroleum code was being prepared.

PRODUCTION

Production of petroleum continued to increase throughout the year, and by December 1963, daily output was averaging 82,854 barrels compared with 69,095 barrels in December 1962. Output of tin increased 6 percent over 1962, and columbite production declined 11 percent. Coal output declined by nearly 39,000 tons to a level only 24,165 tons above that of 1960, the record low for 1959–63.

TABLE 1.—Production of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963

[1] U.S. imports.
[2] Data not available.
[3] Estimate.

TRADE

In 1963, Nigeria's exports rose, causing a significant improvement in the balance of trade; increases in petroleum and tin exports contributed to the rise. Import figures for the first 11 months of 1963 were reported at N£186 million and export and reexport at N£165.2 million.[5]

Estimated figures for the year were imports N£ 204.5 million; and exports, N£180 million showing a visible trade deficit of N£25 million,

[5] U.S. Embassy, Lagos, Nigeria. State Department Dispatch A–503, Feb. 8, 1964, p. 3.

Digitized by Google

a definite improvement over previous years. The United States supplied approximately 8.5 percent of the value of Nigerian total imports for the year.

Continuing a trend, imports from and exports to the European Economic Community markets increased at the expense of Nigeria's largest traditional supplier, the United Kingdom, and of Nigeria's biggest export market, the United States.

There was an increase in total imports due largely to development projects, with their attendant need for raw materials for local processing.

As the result of trade agreements, Japan and the Communist countries also increased their share of Nigerian imports. Association with the EEC improved the long-term outlook of Nigerian trade.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Columbium, concentrate kilograms	1,869,000	2,302,000	United States 1,047,000; United Kingdom 766,000; Netherlands 375,000.
Lead, concentrate	530	620	Portugal 447; Belgium-Luxembourg 126.
Tantalum, concentrate kilograms	11,000	13,400	United States 9,200; United Kingdom 2,400; West Germany 1,600.
Tin:			
Concentrate long tons	10,414	347	Portugal 200; United Kingdom 147.
Metal do	623	8,024	Mainly to United Kingdom.
Other ores and concentrates	51	1,782	United States 1,208.
Nonferrous scrap metal	1,967	1,901	Italy 795; West Germany 280; Japan 271; Netherlands 238.
Iron and steel scrap	18,211	4,624	Japan 2,287; Italy 1,218; Egypt 945.
Mineral fuels:			
Coal thousand tons	52	33	All to Ghana.
Petroleum, crude thousand 42-gallon barrels	16,345	24,553	United Kingdom 16,794; Netherlands 4,238; West Germany 3,390.

TABLE 3.—Import of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962
Metals:			
Aluminum:			
Aluminum roofing, sheets, tiles, ridgings.	1,890	1,994	United Kingdom 840; Austria 766; Belgium-Luxembourg 168.
Aluminum and aluminum alloys (worked or not).	2,961	3,347	United Kingdom 1,094; Belgium-Luxembourg 899; Switzerland 625.
Copper and copper alloys, including wire.	874	1,804	United Kingdom 571; Japan 689; Belgium-Luxembourg 169.
Iron and steel (rolled products)	161,222	141,644	United Kingdom 44,673; Japan 28,433; Belgium-Luxembourg 26,892; United States 15,994; West Germany 9,398.
Lead and lead alloys (worked or not).	1	1	West Germany, United Kingdom.
Silver, unworked and partly worked. troy ounces	562	13,737	United Kingdom 11,683; West Germany 2,032.
Tin and tin alloys long tons	19	74	United Kingdom 61.
Zinc and zinc alloys (worked or not)	36	37	United Kingdom 15; Belgium-Luxembourg 12.

Other refined products—do	84	163	Netherlands 130; United Kingdom 13; Italy 5.
Total petroleum products. do	7,015	6,815	

[1] As officially reported; no further detail available.

COMMODITY REVIEW

METALS

Iron Ore.—Iron ore deposits in Nigeria were not exploited. Deposits occur at Agbaja just north of Lokoja, at the confluence of the Niger and Benue Rivers, and at Enugu. The reserve of Agbaja ore is over 110 million tons of 50 percent iron and a large quantity of lower grade ore.[6] The reserve at Enugu has been reported as upward of 100 million tons containing 30 percent or more iron.

Tests of Nigerian iron ore were underway during 1963 at Canadian plants.[7]

Iron and Steel.—West Africa's first steel rolling mill was opened at Emene near Enugu in July 1962 by Nigersteel Co., Ltd., a joint venture

[6] Steel and Coal. Nigerian Iron and Steel Survey. V. 184, No. 4885, Mar. 2, 1962, p. 423.

[7] U.S. Embassy, Lagos, Nigeria. State Department Dispatch A-503, Feb. 8, 1964, p. 7.

Digitized by Google

between the Government of Eastern Nigeria and Italian interests. It was planned that the mill would use the 12,000 to 15,000 tons of scrap steel generated annually and previously exported, and by so doing, could save Nigeria considerable foreign exchange money. This is Nigeria's first heavy industry and as well as supplying steel for construction and other industrial uses, provides employment and at least limited training in metallurgy.

Attention continued to be given to plans for the development of an integrated iron and steel industry for Nigeria. Sites suggested for the plant are Lokoja and Enugu. There are deposits of iron ore, limestone, and coal in the same general area and should technological problems of the coal and iron ore prove resolvable within economic limits, domestic production of iron and steel would prove of advantage to Nigeria by eliminating the necessity of importing approximately a quarter of a million tons of iron and steel annually. In 1962 Nigeria imported 238,699 tons of construction steel alone valued at N£7,416,000. This item alone was 3.6 percent of the value of total imports.

During the year Nigerian officials participated in meetings sponsored by the Economic Commission for Africa concerning the possibility of establishing a single iron and steel complex for all of West Africa. Port Harcourt has been suggested as a suitable site for such a complex.

Lead.—There was no reported production of lead in 1963 or in 1962. The small quantities mined annually through 1961 came mostly from Plateau Province. Lead-zinc deposits extend discontinuously for about 350 miles in a narrow belt from Ishiagu in the East, through Benue and Adamawa Provinces to Gwana in Bauchi Province. The most important occurrences are South of Abakalika and at Zurak.

Molybdenum.—No report is available on activities during 1963 at the molybdenite lease in Kigom, Zaria Province. In 1962 exploration involving 60 workers was continuing, but no production was reported. Facilities available at the site in 1962 included a crusher, ball mill, classifier, and flotation cells, all of which were reportedly installed to treat molybdenite from surface workings.

Tantalite.—Nigeria's modest production of tantalite declined in 1963 from 1962. The largest percentage of production comes from Benue, Niger, Plateau, and Zaria Provinces.

About 4 percent of the free world's 1963 supply of tantalite came from Nigeria, and the bulk of it was exported to the United States.

Tin and Columbite.—The placer mining of cassiterite and accessory columbite continued to rank second (to petroleum) among Nigerian minerals industries in terms of earnings, and remained a major employer of Nigerian labor, as it was in 1961–62 when it employed an average of 38,847 Africans and 254 non-Africans.[8] The greatest part of the production came from an area around the town of Jos (Plateau Province) on the Bauchi granite plateau.

By far the most important producer was Amalgamated Tin Mines of Nigeria, Ltd., which accounted for over 40 percent of the tin and 36 percent of the columbite produced during the year ended March 31, 1962. In that year 69 other operating firms (including 13 incorpo-

[8] Ministry of Mines and Power. Annual Report of the Mines Division, for the year ended Mar. 31, 1962. Lagos, Nigeria, 1963, p. 9.

Digitized by Google

rated in the United Kingdom, 43 incorporated in Nigeria, and 13 unincorporated but registered Nigerian firms), together with a sizable number of individual operators were responsible for the balance of output. Three other Nigerian companies were listed among incorporated firms but reported no production.

Each of the 70 operating firms recorded some cassiterite production, 36 of them also produced columbite, and 5 recorded tantalite production, with their tantalite output constituting about 24 percent of total Nigerian tantalite production during the year ending March 31, 1962. Of those reporting cassiterite and columbite output, three produced more columbite than cassiterite, on a tonnage basis, and the ratio of production of columbite to that of cassiterite by others was sufficient to make columbite the premium product on a value basis. Presumably, this situation may well have been altered in 1963 when increasing tin prices and declining columbium prices resulted in increased cassiterite output and declining columbite production.

In spite of better tin market conditions, Amalgamated Tin Mines of Nigeria, Ltd., reported a loss of 40 percent in profits due to increased operating costs.[9] Rising costs of production led to merger of some of the smaller companies.

The Nigerian Embel Tin Smelting Co., Ltd., a Portuguese firm, ceased production early in the year after operating for less than 3 years. Makeri Smelting Co., Ltd., a subsidiary of Williams Harvey & Co., Ltd., of the United Kingdom, began operation in the first quarter of 1962 and was the only tin smelter operating at yearend 1963.

Legal Notice No. 72 of 1963, published in the Supplement to the Federation of Nigeria Official Gazette No. 45, v. 50, of July 4, 1963, accorded pioneer status to the smelting and refining of base metals and the manufacture of their alloys. This action reflects the Government's efforts to protect its existing industry.

NONMETALS

Cement.—Nigeria has the raw materials to become self-sufficient in cement production and should attain this status in 3 to 4 years. Cement imports in 1962 were 45 percent lower than in 1960 in spite of increased consumption.

Nigerian Cement Co., operates plants at Nkalaju and Abeokuta, each with a capacity of around 200,000 tons a year using local limestone as a raw material. West African Portland Cement Co. operates a cement plant at Ewehoro near Lagos and in 1963 began expansion to double its capacity.

In September 1963 the Hamburg firm of Coulinho, Caro & Co. announced plans for a 50,000-ton-capacity plant for grinding clinker to produce cement at Keho in the midwest. Another clinker grinding plant is already under construction near Lagos, and another cement plant was under construction at Sokoto in northern Nigeria, by Terrestoal, A. G. Co., of West Germany.

A new concrete products plant was completed by Nigerian Concrete Industries near Lagos, and Asbestos Cement Products Nigeria, Ltd., completed its second plant near Enugu.

[9] U.S. Embassy, Lagos, Nigeria. State Department Dispatch A–503, Feb. 8, 1964, p. 8.

Digitized by Google

A number of concrete product and tile companies continued to operate in Nigeria.

Clay.—Large occurrences of clays for pottery, brick, and tile exist in Nigeria. The growing construction industry in Nigeria has increased demand for construction material including clay products. The several small pottery plants do not supply all the local needs.

The first clay products plant with a capacity of 33,000 tons of hollow clay building blocks annually, using local clay began production late in 1962 at Ikeja.[10]

Clay also was mined and pulverized at Isieke Ihekie, for use as a drilling mud. The capacity was 3,000 bags per day.

Legal Notice No. 109 of 1962, published in the Supplement to the Federation of Nigeria Official Gazette, v. 49, No. 66, of August 16, 1962, declared the manufacture of clay bricks, pipes, and tiles a pioneer industry, and clay bricks, paper, and tiles as the pioneer products of the industry.

Limestone.—The quarrying of limestone has become an important part of the local minerals industry, with the bulk of output being consumed by the cement industry.

An additional use for limestone has developed in the recently built tin smelters. The lessening need to import cement in 1962 effected a savings of almost N£3 million in the balance of import-export trade.

Limestone reserves are abundant at Nkalogue in the east and Abeokuta Province in the west where cement plants have been established. In northern Nigeria, reserves of 109 million and 46 million tons of high-grade crystalline limestone have been proved in Sokoto and Jakura respectively.[11]

Other Nonmetals.—In addition to the commodities reviewed separately, others having possibilities for commercial production on the basis of significant reserves reported included barite, diatomite, feldspar, phosphate, salt brines, stone, and talc.

MINERAL FUELS

Coal.—Coal has played a significant part in the economy of Nigeria; the country has been able to supply all its own needs. Some loss of sales has resulted from the dieselization of railways, and this trend probably will continue. Refining of locally produced petroleum and utilization of natural gas could capture some coal markets. However, the continuing increase in industrialization with its attendant need for more electrification and plant fuel, such as for the recently built tin smelters, may help offset losses.

The proposed construction of an iron and steel mill near Enugu could stimulate coal output. Enugu coal, used in a blend containing 10 to 15 percent pitch, reportedly has been coked successfully under commercial conditions in the United Kingdom. Some thought has also been given to the production of fertilizer and tar fractions from Nigerian coal.

The Nigerian Coal Corp. (incorporated in 1950), the only producer of coal, was operating three mines in the Enugu area at yearend: the

[10] Nigeria Trade Journal. V. II, No. 3, July–September, 1963. p. 103.
[11] Nigeria Trade Journal. V. 10, No. 3, July–September, 1962, p. 118.

Digitized by Google

Okpara (Hayes), opened in 1945; the Ekula, opened in 1956; and the Ribadu, opened in 1961. The Ira mine, opened in 1917, was closed during 1963.

Resources of subbituminous grade coal are reported by the Nigerian Geologic Survey as follows: [12]

Area	Reserve (million metric tons)		
	Indicated	Inferred	Total
Enugu	42.7	12.2	54.9
Ezimo	29.5	17.3	46.8
Orukpa	50.8	7.1	57.9
Okaba	54.9	19.3	74.2
Ogboyoga	83.4	25.4	108.8
Oti	----	6.1	6.1
Inyi	10.2	----	10.2
Total	271.5	87.4	358.9

Over 3,000 are employed by the Nigerian Coal Corp.

Principal markets for Nigerian coal are the Nigerian Railway and the Electricity Corp. of Nigeria, which consumed 47 and 28 percent of production respectively in 1962 according to the company.[13]

An amendment to the Minerals Regulations eliminated royalty payments on coal mined by the Nigerian Coal Corp. effective February 1, 1963.

Petroleum.—Crude petroleum, first shipped from Nigeria in 1958, has become a major factor in Nigeria's industrial development as well as the country's foremost mineral product. Production in 1963 established a new high of 27.6 million barrels.[14] Exports were reported to be 26.7 million barrels which accounted for an appreciable amount of all of Nigerian export trade.

Nigeria's production of crude petroleum in 1962 amounted to 0.28 percent of the world total and 8.3 percent of the African total. The country's share of the world crude oil export trade was 0.73 percent of the world total and almost 9 percent of African crude oil entering the export trade.

The value of crude petroleum exports for the first half of 1963 amounted to N£9.4 million or 10.1 percent of the value of all exports from Nigeria. This compares with N£7.2 million, or 7.9 percent of the total value for 1962.

The value of petroleum export for all of 1962 was N£16.89 or 10.2 percent of the total value of exports.[15]

Offsetting the income from crude petroleum exports was the need to import refined petroleum products. During the first 6 months of 1963, 137.7 million gallons of imports were valued at N£7.2 million.[16] Total value of such imports for 1962 was N£14 million.

Digitized by Google

Nigeria produces more than enough crude oil for its foreseeable needs and when the refinery under construction is completed, the country will be able to supply its own internal needs for refined petroleum products and to produce an exportable excess as well, thus increasing Government revenue from its petroleum resources.

It was announced in April 1963 that a comprehensive petroleum code was being prepared.[17]

Most operations in 1963 were conducted under the terms and procedures for concessions which were outlined in Government Notice No. 2675, published on page 1684 of the Official Gazette of the Federation of Nigeria for December 17, 1959. Also affecting leasing procedures was a March 1961 meeting of prospective operating companies and Government officials at which time the 50–50 profit split was agreed on.[18]

At yearend there were nine established oilfields in Nigeria. Already tied into the Shell-British Petroleum (BP) pipeline system were Bomu (the major producer), Afam, Imo River, Aoara, and Ebubu fields in the east and Obibiri in the west. Plans have been made to tie Vghelli and Rumuekpo in the midwest into the system.

All of the oil and gas showings have occurred in a relatively small area of the country, the Delta section in south-central Nigeria.

In 1963, Shell-BP was the only company to produce crude petroleum; the company has forecast its production at 30.7 million barrels in 1964 and at 43 million barrels in 1965. The company believes the probable Nigerian reserves may be several times the conservative estimate of 300 million barrels often reported.[19]

During 1963 Shell-BP continued drilling additional exploratory and development wells in its extensive onshore holdings, completed plans for new pipelines to bring other producing wells into its gathering system, and progressed slowly on its refinery and loading facilities near Port Harcourt.

During the second quarter of 1963 the first offshore well in Nigeria was spudded by American Overseas Petroleum Co. off Kulama in the Delta. This and two other offshore holes drilled by the same company were dry.

Tennessee Nigeria, Inc., continued exploratory drilling with additional dry holes on the coast, east of Lagos. Gulf and Mobil completed preparations and were ready to start offshore drilling operations. Mobil also commenced a limited operation in the Western Region in 1958.

Shell-BP, in operation in Nigeria since 1937, remained the major concession holder in Nigeria. A French oil company, SAFNEP, secured a license to conduct an area-magnetic survey in the Benue River Basin, hitherto unexplored.

In December 1963, Shell-BP obtained licenses for new pipelines linking its field at Vghelli with the Rumuekpe and Bomu fields and the Bonny oil terminal.[20] A contract was let to construct a pipeline from Imo River fields to the new refinery near Port Harcourt. This adds substantially to Shell's collecting system connecting Afam thru

Digitized by Google

Bomu to the Bonny terminal and to the line from Oloibiri to Port Harcourt.

Early in the year Shell-BP announced plans for doubling its petroleum storage capacity at Bonny terminal to 940,000 barrels.[21] This port, 18 miles south of Port Harcourt, was completed as a deep-water harbor by Shell-BP early in 1961 and is capable of berthing large tankers.

During 1963, work commenced on Nigeria's first refinery at Alese near Port Harcourt. The agreement between the Nigerian Government and Nigerian Petroleum Refining Co., Ltd. (Shell-BP), was signed in 1962. Ownership is: Nigerian Government—50 percent, Shell—25 percent, and British Petroleum—25 percent.

The refinery will consist of a 42,850-barrel-per-day crude distillation facility and a 4,600-barrel-per-day catalytic reforming unit, as well as storage tanks, auxillary services, and a tanker jetty on Okrika Island in the Bonny River. Cost is estimated at US$27 million.

When completed the refinery is expected to process almost 14 million barrels of Nigerian crude oil yearly. Refined products will be gasoline, kerosine, distillate, and residual fuel oils. Much of the refinery output will be exported.[22]

Natural Gas.—Substantial reserves of natural gas exist in Nigeria. Although Shell-BP Development Co. was the only producer of natural gas in 1963, other reserves occur in concessions relinquished by Shell and now controlled by other oil companies. Some reserves also belong to the Government-owned Nigerian Coal Corp. At yearend 1963, two gas pipelines were operating; one supplied 20 million cubic feet of gas daily from the Afam field to the Electricity Corp. of Nigeria to run its power station in Afam; the other supplied 5 million cubic feet daily from the Apara oilfield to the Eastern Nigerian Development Corp., which distributed and sold gas to factories near Port Harcourt. Other gas pipelines were in the planning stage.

The Mineral Industry of the Federation of Rhodesia and Nyasaland

By Thomas C. Denton [1]

THE FEDERATION of Rhodesia and Nyasaland was established on March 24, 1953, and dissolved as of midnight December 31, 1963. It was formed of the following British territories: the self-governing colony of Southern Rhodesia, Northern Rhodesia Protectorate and Nyasaland Protectorate. The divisions of the Federation are discussed separately so that comparison may be made with future issues. However, because foreign trade was reported for the Federation as a whole, the standard format for chapters of this volume has been modified to the extent that principal discussion of trade and trade tables follow the introductory remarks.

The currency of the Federation and of each of its members was the Rhodesia pound, tied to and redeemable in Sterling. The Rhodesian pound (R£) is used throughout the chapter. R£1 equals US$2.80.

TRADE

Exports.—In 1963 the metal and mineral exports of the Federation, exclusive of iron and steel and ferroalloys, totaled R£140.24 million and were 63.2 percent of the value of all domestic exports plus small gold sales within the Federation. The accompanying table of exports in 1961 and 1962 identifies the origin or origins of each item listed.

Imports.—Exact identification of destination within the Federation was not feasible. But with a general knowledge of the economies of the three areas and their relative degree of industrialization, it is roughly estimated that of total imports of metals, minerals, and mineral fuels in recent years, 60 percent went to Southern Rhodesia, 30 percent to Northern Rhodesia, and 10 percent to Nyasaland. The value of imports in 1962 was approximately R£19 million. Three classes of materials accounted for 91 percent of this total value as follows: Liquid fuels, 49 percent; iron and steel semimanufactures, 32 percent; fertilizers, 10 percent. Countries of the Near East, particularly Iran, furnished the great bulk of fuels imported. About 82 percent by value of iron and steel came from the Republic of South Africa. Western European countries supplied most of the fertilizer materials, except that Morocco was the principal source for phosphate rock.

NORTHERN RHODESIA

Northern Rhodesian mineral industry was an important contributor to world mineral supply. In the overall economy of the country the industry is primary. The position results from the large contribution of the copper industry (mining, smelting, and refining). Significant quantities of other metals are also produced, partly as byproducts of the copper industry.

In 1962 the contribution of Northren Rhodesia to world-copper production exclusive of Sino-Soviet Bloc countries was 14.5 percent and the country ranked third after the United States and Chile. In some years the country has ranked second after the United States. In 1962 Northern Rhodesia also contributed 6.1 percent of world cobalt production, 1.9 percent of selenium, and 1.5 percent of zinc. Other output included lead, cadmium, manganese, gold, and silver.

In the economy of the country, the mining industry is the largest contributor to gross domestic product (GDP) and to exchange earnings, as well as the largest employer of industrial labor. Employment in 1963 was about 41,000 Africans and 8,000 Europeans.[2] The value of mineral production was approximately R£125.8 million, of which copper provided R£118.1, nearly 95 percent. Value of production was 60 percent of the R£207.6 million roughly estimated as the GDP of Northern Rhodesia in 1963.[3] As for exchange earnings, both in 1961 and 1962 the value of mineral exports was approximately R£117 million, and of the order of 75 percent of the value of Northern Rhodesia's domestic-product exports. Countries from which mineral exports earned foreign exchange included Republic of South Africa, most of the countries of Western Europe, and the United States.

There was speculation toward the end of 1963 that discussions were in progress between the Northern Rhodesian Government and the British South Africa Co. about transferring the mineral rights of the company to the government. The company owns mineral rights to nearly all of Northern Rhodesia, which would revert to the government in 1984 without compensation. Meanwhile the company pays to the government 20 percent of net revenue derived from exercise of its rights. In the fiscal year ended September 23, 1963, company mining revenue from royalties and other sources was £6,457,000 after deducting the government share of £2,601,000 and £4,162,000 in local taxes.

No industrywide strike occurred during the year, but between June 1962 and September 1963, there were more than 40 separate strikes or work stoppages by African employees. At the large Mufulira copper mine, work was stopped from February 23 until May 2. At Nchanga another large operation, a riot occurred on June 16, 1963, in which nine Africans were killed, and more than a hundred were injured. The riot resulted from rivalry which developed between members of two political parties.

During the year educational and training schemes for Africans continued to be increased both in scope and number.

The Prime Minister of Northern Rhodesia in public addresses has given assurances that when independent, Northern Rhodesia will not

expropriate foreign holdings. Moreover, he has said that expatriates are needed.

SOURCE MATERIAL

Principal sources for information about Northern Rhodesia were official reports of the governments of the Federation and Northern Rhodesia, trade journals, annual minerals reports for the Federation by the American Consulate General, Johannesburg, South Africa, other reports of the Foreign Service of the United States, annual reports of mining companies operating in Northern Rhodesia, the journal of the Chamber of Mines of Rhodesia, and personal observations by the author.

PRODUCTION

A new record of copper production for Northern Rhodesia was achieved in 1963 despite considerable labor unrest. Of the total output of blister copper and electrolytically refined copper, refined production was 438,893 metric tons, or 76.2 percent of output. Refined output has grown steadily in recent years, the increase since 1959 being 18.5 percent. Blister for refining overseas nevertheless was expected to be produced in substantial quantity for some time to come.

Record production of lead and zinc, both from one mine, also was realized in 1963. The increase for lead from 1962 was 32 percent; for zinc, 22 percent.

TRADE

Northern Rhodesia is the principal source of copper for the United Kingdom; for Continental Western Europe, Rhodesia is a major ultimate source; and for most Western European countries, the principal ultimate source along with the Republic of the Congo (Léopoldville). Of tonnage exported in 1962, five European countries took 75 percent, as follows: United Kingdom 44 percent; West Germany 14 percent; Italy 9 percent; France 6 percent; Belgium 2 percent. Of blister copper, three European countries took 78.9 percent as follows: United Kingdom 34.4 percent; West Germany 34.1 percent; Belgium 10.4 percent. As to refined copper (all forms), 75.5 percent went to four countries in Europe as follows: United Kingdom 46.9 percent; Italy 11.9 percent; West Germany 8.8 percent; France 7.9 percent. Exports to the United States totaled 16,585 tons, about half was blister. U.S.S.R. took 4,471 metric tons of blister and 9,408 tons of electrolytic wire bars. Combined exports to Czechoslovakia and Poland were 1,318 tons of blister and 3,353 tons of refined copper.

COMMODITY REVIEW

METALS

Copper and Cobalt.—Northern Rhodesian copper industry (mining, smelting, and refining) is situated in a relatively narrow strip of country known as the Copperbelt. The Belt extends, roughly, from Ndola northwest about 108 kilometers along the common border of Rhodesia and the Republic of the Congo (Léopoldville). Operating in the Belt at the present time are six mining companies and two refining companies. Two of the mining companies also produce byproduct cobalt. Three of the mining companies also have metallurgical plants at their mines.

Anglo American Corp. of South Africa, Ltd., controls three of the mining companies and a refining company. Rhodesian Selection Trust, Ltd., 46.1 percent owned by American Metal Climax, Inc., controls the other companies, and owns outright a fourth mine equipped with smelter, which it operates as a Division of Rhodesian Selection Trust. Table 4 lists the companies, published ore reserves of the mines, and principal metallurgical facilities of both mining and refining companies.

TABLE 4.—Northern Rhodesia copper mining and refining companies, ore reserves and metallurgical facilities, in 1963

	Published ore reserves [1]		Principal metallurgical facilities
	Millions of metric tons	Copper content, percent	
Anglo American group:			
Mining:			
Bancroft Mines, Ltd.	88.9	3.66	Concentrator.
Nchanga Consolidated Copper Mines, Ltd.	[2] 210.4	4.39	Concentrator, leach-electrolysis plant producing cathode copper.
Rhokana Corp., Ltd.	113.0	[2] 2.92	Concentrator, smelter, cobalt plant.
Refining: Rhodesia Copper Refineries, Ltd.			Electrolytic copper refinery, sulfuric acid plant.
Rhodesian Selection Trust group:			
Mining:			
Chambishi Mines, Ltd.	31.2	3.34	None; mine being developed.
Chibuluma Mines, Ltd.	8.8	[4] 4.6	Concentrator, a cobalt-copper matte plant at Ndola.
Mufulira Copper Mines Ltd.	159.3	3.34	Concentrator, smelter, electrolytic copper refinery.
Roan Antelope Mine [5]	84.5	2.92	Concentrator, smelter.
Refining: Ndola Copper Refineries, Ltd.			Electrolytic copper refinery.

[1] As of June 30, 1963, if not shown otherwise.
[2] As of Mar. 31, 1963.
[3] Also appreciable cobalt, but cobalt reserves not reported.
[4] Also 0.15 percent cobalt.
[5] Owned outright by Rhodesian Selection Trust, operated as a Division.

The following are some highlights for the Copperbelt mining industry in 1963.[4]

The industry regained its position as the world's second largest copper producer after the United States.

Copper sold amounted to 624,452 short tons (566,490 metric tons) worth £128 million.

Basic wages and salaries earned by 44,789 employees were R£15.5 million, and total earnings were R£26.3 million.

The contribution of the industry to the net domestic product of Northern Rhodesia was 44 percent and to that of the Federation, 16 percent.

The value of mineral exports was about 92 percent of the total value of merchandise exported from Northern Rhodesia and about 54 percent for merchandise exports from the whole Federation.

With other users on the Copperbelt, a record 2,039 million kilowatt-hours of electricity was consumed.

Coal consumed amounted to 698,983 short tons (634,103 metric tons), nearly 50,000 short tons (45,359 metric tons) more than in 1962.

The fatal accident rate of 0.26 per million hours worked was the lowest ever recorded and compared with 0.48 in 1962. The sharp decline coincided with a safety drive begun in April 1963, chiefly to combat fall of ground, transportation hazards and men falling, the three chief causes of fatal mine accidents.

Rhodesian Selection Trust, Ltd. (RST).—In November 1963, RST announced that it would acquire from American Metal Climax, Inc., the latter's business as sales agent for copper, lead, zinc, and certain

[4] Northern Rhodesia Chamber of Mines. 1963 Year Book. Reported in October 1964 issue of "Horizon," published by Rhodesian Selection Trust Ltd.

Digitized by Google

other nonferrous metals produced by various companies, including those of the RST group. The consideration for the purchase was 1 million RST shares. The transfer was expected to occur on January 1, 1964.

In its report for the fiscal year ended June 30, 1963, RST stated that it was continuing examination of specific areas in Northern Rhodesia that more than 10 years of general exploration had indicated to warrant detailed assessment.

The RST group includes Chambishi Mines, Ltd.; Chibuluma Mines, Ltd.; Mufulira Copper Mines, Ltd.; Roan Antelope Mine; anl Ndola Copper Refineries, Ltd.

Production is expected by mid 1965 from the new open pit mine that Chambishi Mines, Ltd. is developing. Full production of about 26,300 metric tons of copper annually is expected 2 years later. Chambishi has potential for larger output than that for which preparations are underway.

Chibuluma Mines, Ltd. produced 66,597 tons of copper concentrates in the year ended June 30, 1963, which returned 20,340 tons of fire-refinable grade copper. The output was nearly 17 percent larger than in the previous year, as ore was obtained for the first time from the Chibuluma West expansion project.

Production of cobalt-copper concentrates totaled 17,521 metric tons that were sent to the cobalt plant at Ndola where the new matte upgrading section was commissioned early in 1963. Late in the year the upgraded matte was shipped to Belgium for refining.

For the year ended June 30, 1963, planned production of copper by Mufulira Copper Mines, Ltd., was 129,550 metric tons, which is about 85 percent of capacity. A strike interrupted operations for 10 weeks, and actual output was 113,570 tons. This was slightly less than was produced in the previous financial year.

The 1963 operations of the Roan Antelope Mine Division of RST were planned at 85 percent of capacity. Copper production was 77,732 tons, compared to 80,145 tons in the previous financial year. The new Mac Laren shaft was officially opened in August 1963. It is 1,236 meters deep, and the deepest shaft so far sunk from the surface in the Copperbelt. The shaft serves the western end of Roan extension and Muliashi; it is the fourth major service and rock-hoisting shaft to be commissioned. The shaft does not increase production capacity; its establishment was essential to maintain existing capacity.

The annual capacity of the Ndola Copper Refineries, Ltd., for electrolytic copper is about 109,700 tons. Copper refined year ended June 30, 1963 totaled 90,951 tons. The great bulk of copper received for refining came from the smelter of the Roan Antelope mine. Copper was also custom refined for other Copperbelt producers. The quantity of copper refined in 1962–63 was 6,000 tons less than in the previous year due to interruptions resulting from labor disputes.

Anglo American Group of Companies.—The Anglo American group comprises Bancroft Mines, Ltd.; Nchanga Consolidated Mines, Ltd.; Rhokana Corp., Ltd.; and Rhodesia Copper Refineries, Ltd.

During the year ended June 30, 1963 Bancroft Mines, Ltd., continued to encounter difficulties in the No. 1 shaft area, and these became intensified. A leached zone was discovered at the south end of

Digitized by Google

the 1,150 level, extending at least 2,000 feet. About 750,000 tons of ore was indicated to be unpayable in an area where stoping had been planned. In addition, heavy water inflow at the north end of the level delayed progress. As a result of these developments, copper output for the fiscal year fell by 9 percent to 43,847 metric tons, and profit was reduced by nearly 50 percent. It was estimated that 1963–64 production will be reduced to about 40,000 long tons but that it should improve in the following year.

Largely the future of the mine depends on evidence regarding the water problem to be obtained when the upper hanging-wall water zone is tapped. During 1962–63 the average volume of water pumped daily was 48.99 million gallons. Present daily pumping capacity is 71 million gallons—57 million at No. 1 shaft and 14 million at No. 3 shaft.

Nchanga Consolidated Mines, Ltd. completed the first stage of the R£3.7 million plant extensions program with commissioning of the low-grade oxide leaching plant in December 1962. The plant was opened officially in March 1963.

Production for the year ended March 31, 1963, was less than in fiscal year 1961/62 due to strikes by the Northern African Mineworker's Trade Union. Output of finished copper was 178,793 metric tons, comprising 16,367 tons of blister and 162,427 tons of electrolytic copper. The total figure compares with 198,086 tons of copper produced in 1961/62. Sales of blister and electrolytic copper in 1962/63 totaled 174,638 metric tons which compares with 186,608 tons in 1961/62.

At Nchanga West ore hoisted was about 2.7 million metric tons. Development totaled 143,009 feet. Overall average daily volume of water pumped was 17.1 million gallons.

At Nchanga open pit 881,870 metric tons of ore were sent to the concentrator. Overburden removed totaled 4.69 million cubic yards. Of the total, the bucket-wheel excavator and conveyor system handled 2.42 million yards, and shovels and rubber-tired vehicles 2.27 million yards. Ore available at yearend without further stripping was 2.807 million metric tons. From Chingola open pit 337,800 metric tons of ore were milled. Stripping totaled 1.12 million cubic yards. Stripped ore at yearend was nearly 356,000 metric tons.

The concentrator received a total of 3,946,100 metric tons of ore. Copper grade by source of the ore was as follows: Nchanga mine, 6.06 percent; Nchanga open pit, 3.31 percent; and Chingola open pit, 6.08 percent. Some concentrator data were:

	Quantity
Ore milled—metric tons	3,905,000
Feed assay:	
Total copper—percent	5.45
Oxide copper—do	2.37
Sulfide copper—do	3.08
Oxide to sulfide ratio	0.77:1
Percentage recoveries in concentrates:	
Total copper	90.77
Oxide copper	86.45
Sulfide copper	94.09
Copper production in concentrates—metric tons	193,342

Digitized by Google

Production of concentrates was:

Type of concentrate:	Quantity, metric tons	Copper content, percent		
		Total	As oxide	As sulfide
Smelter-grade concentrate	259, 216	44. 41	3. 59	40. 82
High-grade leach concentrate	602, 669	12. 34	11. 21	1. 13
Low-grade leach concentrate	130, 550	2. 94	2. 39	. 55
Concentrate recovered from catchment dam	41, 118	11. 93	10. 09	1. 84

Copper recovery improved over that of the previous year, reaching about 91 percent early in 1963. While in part due to a more favorable ratio of oxide copper to sulfide copper, the improvement mostly resulted from scavenging of low-grade oxide copper being introduced.

Rhokana copper output during the year ended June 30, 1963 was adversely affected by a strike and by a slight decline in grade of ore milled. Statistical details on output were:

	Long tons	Metric tons
Primary production:		
Blister copper	10, 648	10, 819
Anodes for refining	85, 289	86, 659
Cathodes from cobalt plant	3, 071	3, 120
Total	99, 008	100, 598
Finished production:		
Blister copper	10, 648	10, 819
Electrolytic	87, 324	88, 726
Total	97, 972	99, 545

In the cobalt plant, cobalt metal deposited was 1,271 metric tons. This is an increase of nearly 47 percent from the previous year. In addition, 414 kilograms of cobalt in hydroxide was produced. The plant also turned out 4,105 metric tons of copper, of which 75 percent was as cathodes acceptable to the copper refinery. The rest went to the smelter for casting as blister.

Ore hoisted, totaled 5,060,100 metric tons, derived as follows: Nkana, 938,500 tons; South Ore body, 917,300 tons; and Mindola, 3,204,300 tons. Development, including stope preparation and shaft sinking, totaled 342,998 feet. The average volume of water pumped daily was 13.4 million gallons.

Salient statistics for operation of the concentrator during the year are:

		Quantity
Ore milled	metric tons	5, 064, 242
Feed assay:		
Copper	percent	2. 28
Cobalt	do	0. 13
Recoveries:		
Copper in combined concentrates	do	92. 88
Cobalt in cobalt concentrate	do	24. 91
Production of concentrates:		
Copper, 37.02 percent Cu; 0.85 percent Co	metric tons	276, 215
Cobalt, 3.81 percent Co; 12.07 percent Cu	do	41, 741

In March 1963 the concentrator reverted to a return water circuit and a common flotation treatment for the various ores. This reduced reagent consumption and improved flexibility in ore treatment. The reversion also lowered the cost of producing cobalt concentrate but

Digitized by Google

with some decrease in cobalt recovery. It also lowered the copper to cobalt ratio, which improved overall copper extraction.

Rhodesia Copper Refineries, Ltd., owned equally by Rhokana Corp., Ltd., and Nchanga Copper Mines, Ltd., continued to operate its electrolytic copper refinery, as well as the only sulfuric acid plant in the Copperbelt.

Output of finished copper by Refineries, Ltd., in the year ended June 30, 1963, totaled 236,977 metric tons and comprised 23,145 tons of cathodes and 213,832 tons of refined shapes. The latter figure compares with 199,607 tons for the previous year.

Production of 50,384 metric tons of sulfuric acid was 48 percent more than in the previous year. A new plant was commissioned on October 31, 1962, and the two old units later were shut down.

Lead and Zinc.—The Broken Hill mine of the Rhodesian Broken Hill Development Co., Ltd. (controlled by Anglo American Corp.) has accounted for the entire Northern Rhodesian production of lead and zinc for many years. The mine has its own hydroelectric powerplant, an electrolytic zinc refinery, and a lead refinery. In addition, in January 1962 an Imperial smelting furnace was commissioned. Serious difficulties were encountered during the first year of operation of the furnace—particularly rapid-shaft accretion, high-lead volatilization, heavy dross and blue-powder production, and high-zinc content of slag. By early 1963 zinc losses in slag had been reduced to an acceptable figure. The problem of accretion buildup had been virtually solved toward the end of 1963.

Lead output in 1963 was 19,610 metric tons, compared with 14,826 tons in 1962. Zinc production in 1963 totaled 49,450 tons, compared with 40,482 tons in 1962. Additional output in 1963 included 16,859 kilograms of cadmium as extruded pencils. The proved and indicated ore reserve reported at the end of 1962 was 5,351,000 tons, containing 13.5 percent lead and 26.9 percent zinc.

SOUTHERN RHODESIA

Southern Rhodesian mineral industry comprises a large sector of the national economy and is an important contributor to world mineral supply. While the value of output is only about 20 percent of that of Northern Rhodesia, a greater variety of important metals and minerals are produced.

The contribution of the industry in 1963 to the gross domestic product (GDP) of Southern Rhodesia is indicated to have been more than 8 percent. GDP was estimated tentatively at R£294 million.[5] The value of mineral production exclusive of iron and steel and ferroalloys manufactured was R£23.7 million. The industry also contributes substantially to the economy as an employer. At the end of September 1963 it was employing 40,500 Africans and 2,590 non-Africans. The figure for Africans was 2,900 less than at the end of September a year earlier. Exchange earnings of the industry are also important. In 1962 the value of exports was about R£24 million, including R£6,878,180 in gold bullion. Destinations of the exports besides sterling countries

[5] U.S. Consulate General, Salisbury. Airgram A–989, Apr. 6, 1964.

Digitized by Google

included many of the countries of Western Europe, the United States, Japan, and Republic of South Africa.

In 1963 Southern Rhodesia provided 1.1 percent or more of free world output of 8 minerals as follows: Arsenic, white, 1.1 percent; asbestos, 7.6 percent; beryl, 4 percent; chromite, 15.4 percent; columbium-tantalum minerals, new production, 1.7 percent; corundum, 93.8 percent; gold, 1.5 percent; lithium minerals, 92.9 percent. U.S. capital is heavily involved in the chromite-mining industry and substantially, in that of lithium.

Rhodesian Selection Trust Ltd. (RST) continued to center activities in the Lomagundi area, where in 1962 encouraging results were reported in the search for nickel and copper At one location diamond drilling was undertaken; underground work, at another. In addition, RST amended its Exclusive Prospecting Order (EPO) 102 to include gold in the Hartley District, and took out two more for chromite. One of the areas covered looks promising; the other was abandoned late in the year.

Anglo American Corp. of South Africa, Ltd., formed two Southern Rhodesian companies—Northridge, Ltd., and Middleridge—to investigate chromite in the Great Dyke. One area comprises 151 square miles; the other, 34 square miles. Anglo is also investigating iron ore and has started a survey of the gold resources of Southern Rhodesia.

GOVERNMENT POLICIES AND PROGRAMS

Late in 1963 the government proposed the following actions affecting mineral industry:

To increase the size of the fund available to the mining affairs board for loans and operation of the plan for renting equipment to small operators.

To subsidize gold mines operating at a loss, that demonstrated future possibilities, to the extent of the loss or R£3 per ounce, whichever amount was the smaller.

To increase depletion allowance for gold mining from 10 to 15 percent. The depletion allowance for base minerals was to be increased from 2.5 to 5 percent, effective in the tax year beginning April 1, 1964.

To permit mines now allowed to charge capital expenditures on a life-of-the-mine basis to claim future capital expenditures in the year in which incurred.[6]

SOURCE MATERIAL

Major source materials for Southern Rhodesia were the following: (1) Mineral industry trade publications; (2) government publications; (3) company annual reports; (4) dispatches of the Foreign Service of the United States; (5) observation by the author.

PRODUCTION

The total value of mineral industry output in 1963 exclusive of iron and steel and ferroalloys was R£23.73 million, 5 percent less than

[6] Southern Rhodesia, The Chamber of Mines Journal. V. 6, No. 1, January 1964.

Digitized by Google

comparable 1962 output. While more than 40 minerals were produced, 90 percent of total value was contributed by only 5 minerals as follows: Gold, 30 percent; asbestos, 25.3 percent; copper, 13.7 percent; coal, 12.7 percent; chromite, 8.3 percent. The decline in total value in 1963 was largely due to reduced output of asbestos and chrome.

TABLE 5.—Southern Rhodesia: Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:					
Antimony, content of concentrate	94	91	62	55	58

TRADE

Excluding R£6.9 million of gold bullion exported, metal and mineral exports in 1962, including iron and steel and ferroalloys were approximated R£19.9 million. Five items contributed approximately 84 percent of this total as follows: Asbestos, 38.2 percent; pig iron, 14.1 percent; copper, 13.5 percent;[7] chrome, 13.0 percent; ferroalloys, 5.2 percent.

The three largest customers for asbestos by volume were the United Kingdom, West Germany, and the United States. Their shares of total exports were, respectively, 58.7, 8.1, and 3.8 percent. Nearly 90 percent of pig iron exported went to Japan. The United States took 76 percent of chrome exports.

For details on exports and imports, refer to tables 1 and 2.

COMMODITY REVIEW

METALS

Chromium.—Possibly excluding the U.S.S.R., Southern Rhodesia ranks second in the world after the Republic of South Africa for magnitude of chromium resources. Chromite reserves in the Great Dyke of Southern Rhodesia to an inclined depth of 600 feet have been estimated to be nearly 400 million tons. Large reserves also exist in the adjacent Selukwe area. The ore is mostly of metallurgical grade. The bulk of developed reserves is owned by subsidiaries of U.S. companies, which in the aggregate are by far the largest producers.

Southern Rhodesian production in 1963 was 19 percent less than in 1962 and far below peak output of 1960. The decline was due to reduced markets and Russian competition. Export sales, on which the industry chiefly depends, fell to 279,632 metric tons from 391,582 tons in 1962. Exports to the United States were 180,747 tons, 39 percent less than in 1962. At the end of the year some optimism about the outlook for 1964 existed among producers.

Southern Rhodesia has two ferrochrome manufacturers: Rhodesian Alloys, Ltd., in Gwelo and Windsor Ferroalloys (Pvt.), Ltd., at Que Que, a newcomer. Neither company reported production. Exports of ferroalloys, presumably all ferrochromium, in 1962 were 8,208 metric tons valued at R£1,032,334. The quantity exported was 9.5 percent less than in 1961.

Copper.—Major copper mining operations and the smelter are owned or controlled by the South African company, The Messina (Transvaal) Development Co., Ltd. In 1963 Messina reported ore reserves at three Southern Rhodesian operations as follows:

	Quantity, metric tons	*Grade percent copper*
Mangula:		
Proved	13,800,000	1.37
Probable	17,000,000	1.35
Alaska:		
Proved	500,000	2.22
Probable	3,000,000	1.78
Umkando: Proved	958,000	2.86

[7] Value of copper exports is assumed to be the value of blister copper produced in 1962, or R£2.7 million.

Digitized by Google

Production in 1963 of copper in concentrate was 16,773 metric tons, valued at R£3.23 million, the volume being 2,700 metric tons higher than in 1962. Smelter output of blister during the year ended September 30, 1963, was 12,173 tons, 8.3 percent less than the preceding year. The decline resulted from a drop in copper content of Mangula and Alaska concentrates treated. Copper content at yearend was only about 16 to 17 percent.

Gold.—Gold production in 1963 of 566,277 ounces approached the record peak of 570,095 ounces set in 1961. The achievement was largely due to expansion at the Dalny mine, the second largest Southern Rhodesian gold mine, following the Rio Tinto Cam and Motor mine. Dalny is owned by Falcon Mines, Ltd. Ore reserves in 1963 totaled 820,400 short tons, averaging 0.341 ounces gold per ton. While small by South African standards, the reserve probably is the largest in Southern Rhodesia.

While Falcon Mines, Ltd., and two other companies with several mines now account for the bulk of Southern Rhodesia gold production, it is still true that gold mining as such is the major activity of small-scale miners. There are about 150 registered gold mines.

The Chamber of Mines during 1963 investigated the possibility of establishing a gold refinery in Southern Rhodesia. At yearend the study was continuing.

Iron and Steel.—Iron ore production in 1963 was 655,372 metric tons. Exports, all to Japan, totaled 210,564 metric tons and were 42 percent larger than in 1962. Ore for export came from Rhodesian Iron and Steel Co., the Beacon Tor mine near Que Que, controlled by Kobe Steelworks of Japan; Norie mine in the Bulawayo District, owned by Belingwe Mining Investments (Pty.), Ltd.; and a mine adjacent to Norie owned by Bukwa Iron Mining Co. The two companies operating in the Bulawayo District were jointly financing a 4 mile railroad spur to connect the mines with Ingesi, the nearest station on the railroad to Lurenco Marques, Mozambique. The hope was that upon completion of ore-loading facilities in Lourenco Marques scheduled for September 1964, the Rhodesian ore would be competitive on the European market, and the companies would be free from dependence on small-lot shipments to Japan.

Rhodesian Iron & Steel Co. (Risco), the only steel producer, suffered from reduced local demand and reduced staff during 1963. Steel output was about 45,000 metric tons. Pig iron production, however, reached about 229,000 tons; while exports, mostly to Japan, were 216,698 tons. Risco reportedly hoped to sell 61,700 tons of steel locally in 1964, which steel users considered an optimistic figure.

Additional export markets were found late in 1963. Risco reportedly expected to sell about 60,000 metric tons of steel to South Africa and the United Kingdom in 1964, and Japan contracted for 226,800 tons of pig iron.

Tantalite.—Production of tantalite concentrates at 69 metric tons, valued at R£99,253, was 7 percent less than in 1962. The ore reserve of the Benson mine north of Motko, the principal source, is small. Johannesburg Consolidated Investment Co. continued to show interest in Rhodesian tantalite. It took an option on the Portree mine near Umtali.

Digitized by Google

NONMETALS

Asbestos.—Southern Rhodesia markets chrysotile asbestos. More than 60 percent of large production comes from mines controlled by Turner & Newall, Ltd., of the United Kingdom. Their mines in the vicinity of Shabanie are world famous both for capacity and quantity of long-fiber asbestos produced.

The volume of asbestos produced in 1963 in the whole country was virtually the same as in 1962, but value fell by R£1.3 million to R£5,996,760.

Pangoni, the major new asbestos mine, was opened in August 1963 by the Prime Minister. Present capacity for fiber is 10,000 tons annually; in 1964 a decision will be made as to whether capacity will be doubled. If it is doubled, the total investment in the project will be about R£3 million. Pangoni is controlled by Asbestos Investments (Pty.), Ltd., of Johannesburg, which Swiss capital controls.

Lithium.—Bikita Minerals (Pvt.), Ltd., controlled by Selection Trust of London and in which American Metal Climax (New York) is interested, accounts for the entire Southern Rhodesian production of lithium minerals; Bikita is a major world source. Bikita exploits a large pegmatite deposit in the vicinity of Fort Victoria.

Late in 1963, in response to increased orders from the United States, Europe, and Japan, Bikita raised its monthly rate of output from 3,600 metric tons to 5,000 metric tons. The increase required quarrying 27,200 metric tons of ore monthly. Concentration of the ore was by handpicking from belts. Labor force was increased, and additional machinery was provided during the year.

MINERAL FUELS

Coal.—Wankie Colliery Company, Ltd., controlled by Anglo American Corp. of South Africa, Ltd., is the sole coal producer in Southern Rhodesia. The gradual decline in Wankie output in recent years continued in 1963. Production was 85,300 metric tons below 1962, and 1 million tons below the 1957 peak. The reasons for the decline, besides the principal one of competition from the Kariba hydroelectric scheme on the Zambesi River, were increased railroad dieselization and somewhat slow business conditions in Southern Rhodesia. A new threat to coal industry was the oil refinery being built near Umtali.

London & Rhodesian Mining & Land Co., Ltd. (Lonrho), second largest Southern Rhodesian gold producer, proposed to the government construction of a 16-inch, 500-mile pipeline to carry annually 4 million tons of Wankie coal to a seaport for export. Late in 1963 Lonrho also proposed consideration of a 900-mile pipeline to South-West Africa to supply 4 million tons of coal.

Wankie Colliery again investigated and again declined to undertake construction of an oil-from-coal plant. A survey team which last year went overseas found costs still too high.

Petroleum.—At yearend construction of the R£10 million Feruka petroleum refinery 6 kilometers from Umtali and 18 kilometers from the Mozambique border was on schedule. Completion of the project is expected in September 1964. The refinery will be operated by Central African Refinerys (Pvt.), Ltd., owned by a consortium of seven oil companies comprising Mobil Petroleum Corp., Shell, British Pe-

Digitized by Google

troleum, California-Texas Oil Corp., Total Oil Products Rhodesia (Pvt.), Ltd., American Independent Oil Co. and Kuwait National Petroleum Co.

The refinery is being built by Procon, Ltd., a subsidiary of Procon, Inc., of the United States. Crude capacity will be 20,000 barrels a day, although initially the refinery will operate at 65 percent of capacity. It will be one of the most advanced refineries in Africa. It will have a catalytic cracker, making possible the processing of a wide range of crudes. Economics dictated choice of the catalytic cracker inasmuch as virtually no market exists for residual fuel oil in Rhodesia, which has abundant cheap coal and hydroelectric power.

Crude for the refinery will be imported through the Mozambique port, Beira, and transported to Feruka by a 10-inch pipeline about 300 kilometers in length.

NYASALAND

No mineral production was reported for Nyasaland in 1963 except limestone and shale, for which figures were lacking. In the past, production of clinker by Nyasaland Portland Cement Co., Ltd., has been as much as 14,500 metric tons annually.

The bauxite deposits on the Mlange plateau, which the government wants exploited, were the subject of inquiries by the Japanese and an American company. This is perhaps the principal mineral resource presently known in Nyasaland.

The Nyasaland Geological Survey Department continued exploration, including investigation of occurrences of asbestos, bauxite at Lichonya, columbium, copper, gold, graphite, and mica. Results were not promising, except possibly on graphite showings in the Salima area and mica in the Mzimba District, on which more work will be done. In addition, Anglo American Corp. of South Africa, Ltd., continued its investigation of diamond possibilities.

The Mineral Industry of Rwanda

By Thomas G. Murdock [1]

THE REPUBLIC of Rwanda and the adjoining Kingdom of Burundi became independent States on July 1, 1962, following the termination of the United Nations Trusteeship of Ruanda-Urundi, administered by Belgium. Formerly, Ruanda-Urundi had a small but fairly diversified mineral production, but most statistical compilations combined this with that of the former Belgian Congo. Practically all of Ruanda-Urundi's output, except for bastnaesite production which ceased in 1958, came from the area that is now Rwanda.

Mineral production has been generally downward since 1961, and although exact data for 1963 are not available, indications are that record lows were established. Serious racial disturbances in December, between the Tutsis and the Hutus, had a damaging effect on the economy of the country. However, the mining companies were able to continue operations, and little loss of production resulted. Data on metals and minerals imports are available only for 1963, and these were comparatively small for a population of about 3 million.

In 1962 the gross national product (GNP) was RBFr5,700 million (US$114 million),[2] the mineral production was officially valued at RBFr195 million, only 3.7 percent of the GNP.

The mining industry employed a labor force of about 6,250 local inhabitants and 50 Europeans, slightly over one-third of the number engaged 10 years ago when mining employed 19 percent of the total labor force.

GOVERNMENT POLICIES AND PROGRAMS

The political changes following independence reportedly had no adverse effects on the Rwanda mining companies, but very strict exchange control regulations were enforced.

The mining industry continued to be based on the decree of September 24, 1937, made effective in Rwanda in November of that year As provided for by this decree, the Government grants concessions for prospecting and for exploration of mineral deposits to companies and

[1] Mining engineer, Division of International Activities.

[2] Rwanda Burundi (RB) francs are the monetary units used in this chapter. The official exchange rate was RBFr1=US$0.02. The unofficial rate was US$1 at RBFr100.

Digitized by Google

individuals meeting certain qualifications. Mining permits are for 30 years in the case of surface deposits and for 50 years for deposits at depth.

A Rwandese law, enacted during the year and made retroactive to January 1, stipulated that mines which have not been operative for the 3 previous years shall revert to public ownership. The Government announced plans to expand production by putting new mining legislation into effect. Prospecting rights will continue to be granted but could be awarded by communal administrations in the case of prospecting by individuals. Buying agencies were to be set up. By these measures the Government hoped to double output within 5 years. Expanded production was also dependent upon enlarging the capacity of hydroelectric stations.

A European Common Market prospecting team visited Rwanda, in an effort to replace the abandoned private prospecting by a governmental organization. Expectations were that work would be concentrated mainly in areas where prospects seemed more favorable, the Congo-Nile Divide and the Ruhengeri and Kagera regions. A program of detailed geological mapping was scheduled for implementation by the Government agency concerned, in collaboration with the Royal Central African Museum, of Tervueren, Belgium.

SOURCE MATERIAL

Some information was supplied by the U.S. Embassy in Kigali, but that contained in an English publication [3] has provided practically all of this chapter except for the trade data from a publication of the Republic of Rwanda.

PRODUCTION

Individual commodities showed considerable fluctuations in output during 1959–63. The overall trend is best reflected in the following total value of annual production: 1959, RBFr161 million; 1960, RBFr199 million; 1961, RBFr233 million; 1962, RBFr196 million; and 1963 RBFr166 million (estimate). Market prices have had a minimum effect on the downward trend of most commodities; the decrease from the 1961 high has resulted from local conditions including limited exploration, depletion of the amblygonite deposits, the generally decreasing tenors of ground mined, and the suspension of operations by one of the larger companies. The continual production of beryl and tin ore at above 1959 levels has offset in part the lower production of the other minerals. Unsettled conditions in Rwanda and adjacent countries during latter years have prevented any increase output from mines with otherwise good operating conditions and reserve position.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:					
Beryl	170	281	476	357	[2] 228
Columbium and tantalum concentrate kilograms [3]	64,000	48,000	46,000	39,000	[2] 30,000
Gold troy ounces	3,119	1,566	900	[2] 900	[2] 500
Tin content of ore [4] long tons	1,124	1,277	1,474	[2] 1,440	[2] 1,250
Tungsten ore and concentrate (60-percent WO_3 basis)	155	457	666	150	[2] 100
Nonmetals:					
Lithium, amblygonite	2,690	2,381	1,682	326	[2] 268

[1] In addition, construction materials are produced in Rwanda, but no quantitative data are available.
[2] Estimate.
[3] Includes small quantities from adjacent Burundi (2,000 kilograms reported in 1962, only year for which data are available).
[4] Includes small quantities produced in Burundi; except for 1962 and 1963 when these were 35 and 25 tons, respectively, no differentiation is possible.

TRADE

Data on trade in minerals and metals prior to 1963 are not available for Rwanda alone. Exports have been equal to production except for minor stock changes. In 1961 the total value of exports was RBFr220 million, 17 percent of the total combined exports of Rwanda and Burundi. In 1963 Rwanda's recorded exports of metals and minerals were valued at RBFr144 million, 80 percent of the country's total exports. Tin ores and mixtures of tin and columbium minerals totaled RBFr141 million. Recorded imports of metals and minerals (including some metal manufactures) in 1963 were valued at RBFr52 million, 21 percent of all imports.

Data on destination of the exports of metals are not available; Belgium received 80 percent of all exports and probably a higher proportion of most of the mineral commodities. Belgium supplied only 24 percent of all imports. The suppliers of petroleum refinery products, Saudi Arabia and Iran, were the leading sources of metal and mineral imports, with 35 and 26 percent, respectively. No minerals and metals trade with the United States was identifiable from Rwanda statistics; however, in past years a part of the beryl and columbite-tantalite production went to that country but was combined with that from the Republic of the Congo (Léopoldville).

TABLE 2.—Principal exports of metals and minerals in 1963 [1]

(Metric tons unless otherwise specified)

Commodity [2]	Metric tons	Value (thousand RB francs)
Aluminum [3]	4	196
Bismuth ore and concentrate [4]	27	2,503
Tantalum concentrate	2	266
Tin ore and concentrate:		
Cassiterite long tons	1,204	113,424
Cassiterite-tantalite-columbite	285	27,283
Tungsten ore and concentrate	10	245
Total value		143,917

[1] Data for earlier years or showing destinations not available. Belgium was principal destination of most exports.
[2] In addition, lithium (amblygonite) was exported and perhaps some gold from production of previous years; quantities not available.
[3] Designated as unmanufactured but may have been scrap.
[4] Not shown by production; may have originated outside of Rwanda.

TABLE 3.—Principal imports of metals and minerals in 1963 [1]

Commodity	Metric tons	Value (thousand RB francs)
Metals: [2]		
Aluminum	420	1,816
Copper	17	945
Iron and steel	464	8,900
Nonmetals:		
Cement and salt [3]	1,436	3,694
Mineral fuels:		
Petroleum refinery products [4]	6,488	36,673
Total value		52,028

[1] Data for earlier years or showing sources not available; Belgium was principal source of imports other than mineral fuels.
[2] Manufactures included.
[3] Not available separately.
[4] Customs classification is "mineral fuels" but is believed to consist entirely of these products. Principal suppliers were Saudi Arabia (3,445 tons) and Iran (2,132 tons). Lubricants may not have been included.

COMMODITY REVIEW

METALS

Beryl.—The decreased output of beryl since 1961 is partly the result of the suspension of operations by Compagnie Minière du Ruanda-Urundi (MIRUDI), a formerly important producer of beryl, cassiterite, and columbite-tantalite. The 1963 production was apparently all by Société des Mines d'Étain du Ruanda-Urundi (MINETAIN), a Belgian company associated with the Société Générale Group, and with widely dispersed activities in Rwanda. The beryl production is a byproduct of the mining of cassiterite with which it is associated in certain pegmatite dikes. Output is not proportionate to that of cassiterite as some zones in the pegmatite bodies are richer in beryl than others and only a part of the Rwanda cassiterite comes from

Digitized by Google

pegmatites; quartz veins contribute most of the remainder. The beryl is obtained by hand sorting from the pegmatite and beryllium oxide content is 10 to 13 percent.

Columbium-Tantalum.—The pentoxides of these metals, in an intimate association with each other, continued to be mined on a small scale and it is believed that the production during recent years has been entirely as concentrates separated from a mixture of columbite-tantalite and cassiterite mined from pegmatites. MINETAIN continued to operate the plant, located at Katumba, for separating cassiterite from the mixture and as the leading producer may have accounted for all the 1963 output. MIRUDI was formerly a producer of columbite-tantalite, and the decline during recent years was partly due to the suspension of their operations. In 1962 MINETAIN produced 306 metric tons of mixed concentrates; the tantalite-columbite contained apparently constituted about 13 percent of the total. Rwanda columbite-tantalite assays 70 to 75 percent combined pentoxides.

Gold.—The decreased gold production was both a continuation of an earlier trend and a result of increased mining by unauthorized operators, attributed to the attraction of strong currency in the neighboring countries and to a falling off in police supervision. The problem became serious and official production was brought to almost a complete standstill. Data on sources of production in 1963 are not available; in 1950 output reached 7,587 ounces and was mainly from operations of MINETAIN, an associated company, and one or two individual miners.

Tin.—The tin ore production came mainly from the mines of Compagnie Géologique et Minière du Ruanda (GEORUANDA), at Rwinkwavu; Société Minière de Muhinga et de Kigali, at Rutongo; and of MINETAIN, at Katumba, Musha, and in the vicinity of the Congo-Nile Divide. A small output may have been maintained by Compagnie de Recherches et d'Exploitation Minière (COREM) and some of the various individual miners formerly active back in 1953 when the contained tin production of Rwanda and Burundi together was 2,040 long tons. Many of the occurrences exploited in the past are outcrops, but progressive exhaustion of the surface deposits has forced the producers to operate at increasing depths. After an initial concentration by sluices or washers the cassiterite is treated in Harz jigs; the marketable product contains 72 to 74 percent tin. The tin concentrates are normally exported to Hoboken, Belgium, for smelting and refining. In 1962 underground mining accounted for 56 percent of all cassiterite mined; in 1963 this dropped to 45 percent mainly due to the flooding of the mine workings by heavy rains. Difficulties of control and supervision due to the widely separated plants were another factor leading to the decreased output. The ground mined averaged from 1.2 to 1.5 kilograms of cassiterite, columbite-tantalite, or wolframite per cubic meter. The operators have had a natural tendency to exploit successively the richer parts of each deposit; this and decreased prospecting have accounted in part for the reduction of output since the 1956 peak, but the international restrictions of tin for the 1958–60 period were a more important cause. Rwanda did not participate in 1961 in the International Tin Agreement and thus was not bound by the quota scheme.

Digitized by Google

Tungsten.—There was a remarkable recovery in tungsten ore production in 1961, but this was only temporary and 1963 marked a new low. Little data on sources of production are available; MINETAIN's output through June was at an annual rate of 59 percent below 1962. The large Kifuruwe and Kagogo mines in the Rubengeri area, operated by individuals, are believed to have been the major producers, as in the past.

NONMETALS

Lithium.—MINETAIN continued production of amblygonite from its Rongi mine, the only important deposit known. Reserves were practically exhausted at the end of 1961, and subsequent work has been limited to extracting the small tonnage remaining.

MINERAL FUELS

Natural Gas.—It was reported that a deposit of methane in the waters of Lake Kivu was to be exploited, but little detailed information is available. Known for several years, the deposit was investigated in 1961 by the Union Chimique Belge, and gas reserve was placed at 50 billion cubic meters. Original plans were to install a tapping station on a cape near Kisenyi, on Lake Kivu, and furnish the local brewery with about 400 cubic meters per hour of purified gas obtained from about 1,500 cubic meters of crude gas extracted from the bottom of the lake. About 2 tons of byproduct carbon dioxide might be obtained and used for making dry ice, a market for which would be provided by conservation of fresh food and fish produced by the local industry. The preparation of bottled methane for household use was mentioned as an ultimate objective.

The Mineral Industry of Senegal

By Thomas G. Murdock [1]

MINING in Senegal was limited mainly to the recovery of titanium and zirconium minerals from beach sands of the Atlantic coast and to the production of phosphate rock. While titanium mineral production declined in 1963, this was a temporary condition and progress was made on the installation of new facilities for a substantial increase in output. Senegal's titanium and zirconium mineral production constituted a small fraction of world total; however, it continued to be a principal source for French industries. Phosphate rock production was below the 1962 level; it comprised only 1.2 percent of the world total but was unique because part of it was the rare aluminum phosphate, and the calcium phosphate had a P_2O_5 content greater than that of many competitive producers. Completion of Senegal's only oil refinery at the end of the year was a significant step to an improved mineral economy. The refinery is to operate entirely on imported crude oil. The search for important petroleum deposits proved disappointing.

In 1962 the gross national product (GNP) was CFAF141,120 million (US$576 million); [2] the mineral production had an estimated value of CFAF2,979 million (2 percent of GNP), exclusive of petroleum and building materials other than cement and for which no basis for an estimate was available. In 1963 the estimated total production value declined to CFAF2,902 million.

Current data on employment by the extractive industries are not available. In 1959 their labor force comprised 1,906 workers; this has increased appreciably with the opening of the Taiba phosphate mine in 1960 and its subsequent growth in output. Expectations were that 190 people would be employed in the petroleum refinery. Regardless of the size of the total labor force, the minerals industry employed only a small part of the 27,000 in all industrial activities and of the 100,000 wage earners out of the 3.1 million population.

At yearend U.S. investments in the Senegal minerals industry consisted of the International Minerals & Chemical Corp.'s holdings in the leading phosphate company and of U.S. petroleum companies in the petroleum refinery. Some participation in oil exploration may have been still in effect.

GOVERNMENT POLICIES AND PROGRAMS[3]

No legislation of specific application to the extractive industries was reported in 1963. A liberal, nondiscriminatory investment code was enacted as Law 61–33 on March 22, 1962. The code was designed to encourage private investments, both foreign and domestic in projects which conform to Senegal's 4-year-development plan for 1961–64. The code guaranteed the general principles of freedom for nationals of all countries to establish businesses in Senegal. Investors were accorded certain benefits, such as the reduction or exoneration of the tax on profits from industry or commerce for 5 years, a reduction of the entry tax for equipment and raw-material imports, a waiver of customs duties, and an exemption from certain taxes on goods which have been reworked in Senegal and then reexported.

A foreign investor may sign a special founding agreement with the Government by virtue of which he receives additional legal, financial, and other assurances in return for his commitment to carry out a certain program. This agreement is extended only to domestic and foreign investors proposing a minimum investment over 3 years of CFAF1,000 million. Investments in mining, ore transforming, metalworking, and petroleum refining, and in projects set forth in the 4-year plan are subject to what is known as the long-run tax benefit program. Following the enactment of the investment code, an investment guarantee agreement was signed between Senegal and the United States, and thus U.S. investments can be guaranteed against inconvertibility, expropriation, and war losses.

The 4-year plan included a systematic inventory of the subsoil resources, and in 1963 the comprehensive program of geological investigations was continued as in previous years. Indications are that petroleum exploration was on a reduced scale. Expectations were that for 1961–64 CFAF4,900 million would be spent in oil exploration; through 1960 expenditures in this search totaled CFAF7,350 million. An evaluation of the 4-year plan in general, made in September, showed overexpenditures for administrative overhead, education, and infrastructure, and that productive investments were behind schedule. Steps were taken to further encourage private investments, to institute an austerity program in Government operations, to raise taxes, and to reduce imports. Political and economic relations with Mali were normalized, bringing the possibility of significant economic benefits to Senegal once Mali's currency problems are resolved.

SOURCE MATERIAL

Data on production and developments are from dispatches of the U.S. Embassy in Dakar, augmented by technical journals.[4] The latter have also provided most of the background information. Foreign trade statistics are inadequate for a complete, detailed analysis;

[3] U.S. Department of Commerce. Basic Data on the Economy of Senegal. World Trade Information Service. Pt. 1, No. 62–23, April 1962, p. 10.

World Oil. V. 157, No. 3, Aug. 15, 1963, p. 1960.

Digitized by Google

some information has been provided by the Embassy and by publications of the Senegalese and French Governments and the European Economic Community (EEC). For some commodities data on trade shown by different sources do not agree; in these cases efforts have been made to reconcile these or to use those which appear most plausible.

PRODUCTION

The 1959–63 period was characterized by an irregularly declining output of ilmenite and zircon and greatly increased production of phosphate rock. The former was due to operating conditions attending the exploitation of the beach-sand deposits; the latter was entirely the result of opening up the calcium phosphate deposits at Taiba in 1960, with a spectacular immediate rise through 1962 and a subsequent small decline. Output of aluminum phosphate rose through 1962 with a small drop in 1963. Cement production has shown a small increase, and salt output has remained below that of 1959. Senegal produces most of its requirements for construction materials; however, no quantitative data are available. Indications are that 1963 construction activities were slightly below those of 1962, with a decline from 174,800 to 156,300 square meters (estimated) of building permits issued in Dakar.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:					
Titanium concentrate:

Petroleum:					
Crude		1,626	2,242	463	
Refinery products: [5]					
Gasoline					3,481
Kerosine					665
Distillate fuel oil					3,430
Residual fuel oil					3,263
Total					10,839

[1] In addition, building materials other than cement are produced, but no quantitative data are available.
[2] Final figure; supersedes figure given in commodity chapter of volume I.
[3] Includes production of Mauritania, estimated at 500 to 800 tons per year.
[4] Estimate.
[5] Small-scale refinery operations began in December 1963.

TRADE

Data available on metals and minerals traded by Senegal were limited to the major commodities; in 1962 exports of these were valued at CFAF1,898 million and constituted 6 percent of all exports (CFAF 1,685 million and 5 percent in 1961). In 1962 phosphate rock exports

Digitized by Google

were worth CFAF1,359 million; the value of other exports follows: Phosphatic fertilizers, CFAF211 million; scrap metals, CFAF155 million; titanium concentrates, CFAF142 million; and salt, CFAF31 million. The 1962 major metal and mineral imports were valued at CFAF3,899 million, comprising 10 percent of all imports (CFAF3,624 million and 10 percent in 1961). In 1962 they consisted of metals, CFAF1,495 million; nonmetals, CFAF322 million; and mineral fuels, CFAF2,082 million.

TABLE 2.—Major exports of metals and minerals
(Metric tons)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Copper, scrap	641	625	Italy 246; [1] France 193; [1] Belgium-Luxembourg 70. [1]
Iron and steel, scrap	11,382	10,103	Mainly to Japan; Italy 405. [1]
Titanium concentrate	21,659	22,962	Mainly to France.
Nonmetals:			
Fertilizers, phosphatic [2]	18,981	32,810	([3]).
Phosphate rock:			
Aluminum phosphate	90,268	110,920	([3]).
Calcium phosphate	308,559	342,043	France 96,120; West Germany 88,493; Japan 54,535; Netherlands 33,301.

[1] Imports from Senegal by country stated.
[2] Includes dehydrated aluminum phosphate and products marketed under trade names of Baylifos, Polyphos, and Phospal. Data on dehydrated aluminum phosphate included are not available for 1961; 27,965 tons apparently were included in 1962.
[3] Data not available.

Source: Bulletin Statistique et Économique Mensuel. No. 11, 1963. European Economic Community. Foreign Trade Statistics, 1962. August 1963.

Detailed valuation of Senegal's 1962 metals and mineral trade with other countries was not available. France undoubtedly continued as the leading trading partner, as was reflected by its share in Senegal's total trade (86 percent of all exports and 65 percent of all imports). In 1962 EEC exports to Senegal were reportedly worth CFAF2,880 million. Minerals and metals were insignificant in 1962 trade with the United States; this trade totaled CFAF42 million for exports of all commodities and CFAF1,477 million for corresponding imports.

On the basis of data through November, the 1963 exports of major metal and mineral commodities, enumerated for 1962, were estimated at CFAF2,081 million. The imports had an estimated value of CFAF3,688 million.

COMMODITY REVIEW

METALS

Iron Ore.—No progress was reported toward opening up the iron ore deposit in the Kedougou area. Despite a reserve of 40 million metric tons containing 62 to 64 percent iron, the 750-kilometer distance from the coast has been the major handicap to development.

Iron and Steel.—Work continued on plans for the construction of a steel plant in Senegal, to be owned jointly by the Senegalese Government and Compagnie Métallurgique et Minière, a French firm holding the majority of the stock. The proposed plant was to have an estimated annual capacity of 30,000 metric tons, and construction was scheduled to begin in 1964. Initially the installation was planned to remelt scrap collected in Senegal, previously exported to Japan and Italy at the rate of about 11,000 tons per year. Scrap also was to be imported from neighboring African States, and consideration was given also to possibilities of using Mauritanian iron ore, if freight rates on the small volume required were not prohibitive.

Titanium and Zircon.[5]—Société Minière Gaziello et Compagnie (SMG), the wholly-owned subsidiary of the French firm, Thann et Mulhouse, continued mining and treatment of beach sands for the recovery of ilmenite, rutile, and zircon. The decreased output of ilmenite, the main product, was due to the poor condition of the old plant at Djifère-Sangomar near the mouth of the Saloum River and

[5] Metal Bulletin (London). No. 4807, June 25, 1963, p. 21.

Digitized by Google

the lower grade sands worked. The maintenance of rutile production at the 1962 level and the 31-percent increase in zircon was apparently due to working areas rich in these minerals, or perhaps to re-treating sands from which the ilmenite had already been recovered. SMG began work on a new plant, based on virgin deposits in the M'Bour-Joal area, which would have an annual capacity of 60,000 tons of ilmenite, 10,000 tons of zircon, and 1,000 tons of rutile. The new installation was expected to begin operations in the second half of 1964; it was to consist essentially of a mobile plant for separation of the heavy minerals from the sands and a fixed unit for a final enrichment and separation of the different products. Cost of the project was reported at CFAF550 million. The sands to be fed to the new plant are from old dunes where the mineralization is more uniform than in the irregular and dispersed sands of the open beaches worked in the past.

Senegal ilmenite contains 58 percent titania and rutile, 96 percent; the zircon contains 66 percent zirconia. France has provided the principal market for these products. Thann et Mulhouse and their associated Les Produits du Titane are expected to use the increased production of ilmenite in titanium pigments; some rutile and zircon might be sold on the open market. Exports in 1963 were ilmenite, 11,945 metric tons; rutile, 906 tons; and zircon, 3,279 tons.

NONMETALS

Phosphate Rock.—Compagnie Senegalaise des Phosphates de Taida accounted for the entire output of calcium phosphate; 1963 production was slightly below that of 1962 because of large stocks at yearend. Exports established a record high of 454,878 metric tons; the principal destinations were West Germany, 165,540 tons; Republic of South Africa, 68,069 tons; Japan, 65,720 tons; Netherlands, 44,636 tons; United Kingdom, 39,868 tons; and France, 36,446 tons. The mines are at Taiba, near Dakar, and the deposits were estimated in 1963 to contain a reserve of 100 million metric tons, of which 40 million tons had been proved at a depth of 20 meters and 60 million tons at 30 meters. The phosphate seam was stated to be at least 6.5 meters thick. Waste stripping and phosphate rock mining were by draglines; bucket capacity was 18 cubic meters for stripping and 6 for mining. After a preliminary sizing and removal of quartz, the ore was upgraded by two-stage beneficiation. The first stage employed hydrocyclones for the removal of the argillaceous and very fine elements and the second, flotation with fatty acid reagent, in which the siliceous elements and the oxides of iron and aluminum were depressed. After filtration and drying in a rotary kiln, 2.4 meters in diameter and 24 meters long, the marketable product contains less than 1.5 percent moisture, and 37.6 percent P_2O_5.

The Taiba company was founded in 1957 and capitalized at CFAF2,000 million; the French Government's Bureau de Recherches Géologique et Minières contributed 35.83 percent, the Senegalese Government, 4.17 percent, and the remainder was provided by French banking, chemical, and phopshate groups. International Minerals & Chemical Corp., Skokie, Ill., became associated with Taiba in 1962,

Digitized by Google

and subsequently it was reported that capital had been increased to CFAF2,275 million and that the U.S. firm's participation eventually would reach 25 percent. During 1963 the Taiba company marketed its output independently of the Union Phosphatière Africaine Sales Organization, following the termination of its agreement with that organization at the end of 1962. International Minerals & Chemical Corp., as a leading U.S. phosphate exporter, undoubtedly was able to facilitate greatly the marketing of the Taiba phosphate. Productive capacity at Taiba was 600,000 metric tons, and in anticipation of a 60-percent increase in sales, measures were being taken to increase production sharply. In December a sales agreement was negotiated with United Kingdom's Imperial Chemical Industries, Ltd., for the sale of 150,000 tons of calcium phosphate in 1964.

Senegal's production of aluminum phosphate rock continued to come from the Thiès mine, east of Taiba, operated by Compagnie de Produits Chimiques et Électrométallurgiques Péchiney, a minor shareholder in the Taiba company. The mine reserve was estimated in 1962 at 37 million metric tons containing 29.5 percent P_2O_5 and 100 million tons if 28-percent material is included. Production declined 12 percent because of large stocks from the previous year. Exports in 1963 were 110,000 metric tons (108,000 tons to France and 2,000 tons to New Zealand). A part of the production continued to be calcined in a plant at Lam-Lam and the clinker finely ground at Sète, and marketed locally, exported as dehydrated aluminum phosphate or under the trade names of Phosphal, Polyphos and Bayliphos. Phosphal contains 34 percent P_2O_5, and this is assimilable by plants. Polyphos is similar to Phosphal and has begun to find markets as animal food. In 1962 and 1963 production and exports of dehydrated aluminum phosphate and special products were as follows:

	1962		1963	
	Production (metric tons)	Exports [1] (metric tons)	Production (metric tons)	Exports (metric tons)
Dehydrated aluminum phosphate	41,681	33,940	17,710	18,900
Phosphal	5,669	3,843	28,594	2,160
Polyphos		135		
Bayliphos	1,621	1,997	14,565	193

[1] Official trade statistics listed exports of phosphatic fertilizers at 32,810 tons; this apparently included 27,965 tons of dehydrated aluminum phosphate, and the remainder was exported as "aluminum phosphate."

MINERAL FUELS

Petroleum.—Little data on activity in 1963 petroleum exploration and production are available. Indications are that there were no important developments and the production from the single well of Société Africaine des Pétroles (SAP), 30 kilometers from Dakar, was insignificant, if there was any output at all. In addition to SAP, Société des Pétroles du Senegal (SPS) and Compagnie des Pétroles Total de l'Afrique de l'Ouest (COPETAO) were formerly active in Senegal. SAP did some work as operator of the St. Louis permit north of Dakar. This permit was held in about equal shares by SAP,

Digitized by Google

Compagnie de Participations de Recherches et d'Exploitations Pétroliers (COPAREX), Continental Oil Co., and Cities Service; however, the permit was released at the beginning of 1963. SPS dropped its onshore concession in 1962 but subsequently applied for and was granted an offshore permit between SAP's Dakar permit and the Gambian frontier. COPETAO held the Kolda permit (21,340 square kilometers), partly offshore.

The 600,000-ton-per-year petroleum refinery of Société Africaine de Raffinage (SAR), under construction since 1961 at M'Bao near Dakar, went on stream on December 8. SAR was formed by an association of French petroleum interests (41.8 percent); the Senegalese Government (10 percent); British Petroleum, Mobil Oil, Shell Oil, and Texas Oil (11.8 percent each); and Esso (1 percent). During December, 18,357 tons of crude was processed although the refinery was not completely operational; the final work was to be completed by late February 1964. Investments for the refinery amounted to about CFAF4,000 million; at a slight additional cost capacity could be doubled. Five-sixths of the crude-oil supply is expected to come from the Hassi-Messaoud field in the Algerian Sahara and one-sixth from Gabon. The refinery was expected to bring CFAF500 million annually into the Senegalese economy.

New taxes on petroleum products were established effective July 1; expectations were that these would bring in an additional revenue of CFAF250 million annually.

The Mineral Industry of Sierra Leone

By Thomas C. Denton [1]

PRODUCTION of minerals for export continued to be the prime sector of the economy of Sierra Leone, a former British Colony and Protectorate that became independent on April 27, 1961. The industry remained the largest contributor to national cash income, the largest foreign exchange earner, and probably the largest employer of industrial labor.

In 1963, output consisted of diamonds (alluvial), iron ore, bauxite, and small quantities of gold (alluvial). By value the country generally has ranked about third among diamond producers of the world, after Republic of South Africa and Southwest Africa. Small quantities of chromite were produced until 1962, when operations were suspended. Exploration of a deposit of heavy minerals, particularly rutile, near the coast was in progress at yearend and may result in a new mining operation for the country.

Diamonds were recovered by the British company, Sierra Leone Selection Trust, Ltd.; from two large widely separated concessions called Yengema and Kono; and by many small operators. Iron ore was produced exclusively by the British company, Sierra Leone Development Co., Ltd., from the Marampa deposit. Bauxite mining was in the hands of Sierra Leone Ore & Metal Co. (SLOM) owned by Aluminum-Industrie-Aktien-Gesellshaft of Zurich, Switzerland. The heavy minerals project was a joint venture of Pittsburgh Plate Glass Co. and British Titan Products Co., Ltd. who have been exploring near Gbangbamg for 7 years.

Estimates of the gross national product (GNP) of Sierra Leone in West African pounds (WA£) [2] range from WA£54 million to WA£98 million,[3] and the value of mineral production in 1963 was about WA£17.7 million.[4] Thus the contribution of the mineral industry to GNP was between 18 and 33 percent.

In recent years minerals have provided about 75 percent of the total value of domestic exports, more than balancing expenditures for mineral and metal imports and contributing in major degree to the overall favorable trade balance.

In 1961 organized mining operations had more than 6,000 employees, with 207 occupying supervisory and executive positions. The estimated number of persons engaged in small-scale diamond mining during the wet and dry seasons was, respectively, 17,500 and 46,000. These figures are the most recent available; it is believed that in 1963

[1] Africa specialist, Division of International Activities.

[4] To obtain the figure, export values were used when production values were unavailable.

Digitized by Google

organized operations had about the same number of employees as in 1961, but that the number of small-scale diamond miners had decreased substantially.

Principal mineral development in 1963 was commencement of bauxite mining late in the year; and prospects appeared good that rutile mining would soon begin.

Throughout 1963 the Government of Sierra Leone continued its sincere open-door policy to foreign investment.[5]

SOURCE MATERIAL

Source material for this chapter comprised chiefly dispatches from the U.S. Embassy in Freetown, notably A–192, March 13, 1964; semiannual Summary, July 1–December 31, 1963; reports of the Mines and Geological Departments of Sierra Leone; company reports; and articles appearing in trade journals.

PRODUCTION

The value of minerals produced in 1963 was WA£17.7 million; in 1962 it was WA£16.4 million.[6] In both years diamonds provided about 70 percent of total value, and iron ore virtually all of the remaining 30 percent. Bauxite should contribute significantly in 1964, when exports are expected to be about 100,000 tons.

[2] Exports.
[3] Production suspended in 1962.
[4] Partly estimated.
[5] Data not available.

TRADE

Sierra Leone has a favorable balance of trade in metals, minerals, and semimanufactures of mineral origin, despite the lack of mineral fuels resources. Net exports for these commodities in 1961 and 1962 were, respectively, WA£18.6 million and WA£10.2 million.

Domestic mineral exports in 1961 were WA£20.8 million, comprising nearly 83 percent of all domestic exports by value. Diamonds ac-

[6] Value included export values when production values were unavailable.

Digitized by Google

counted for 76 percent of the total and iron ore for virtually all of the remainder.

While the great bulk of the diamonds exported went first to the United Kingdom, major ultimate destinations were the United States and Western European countries. Historically the United Kingdom has also been by far the largest recipient of iron ore. But beginning in 1961, and through the third quarter of 1963, either or both West Germany and the Netherlands have taken larger tonnages than the United Kingdom. Of 2 million tons exported in 1962, West Germany took 35 percent; the Netherlands, 32 percent, and the United Kingdom, 29 percent.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Chromite	9,132	9,507	All to United Kingdom.
Iron ore:			
Fines—thousand tons	133	108	All to Netherlands.

Ferromax—do	1	1	Mainly to West Germany.
Total—do	1,786	2,015	
Scrap, ferrous and nonferrous metals	6,546	3,508	Japan 1,770; Netherlands 915; Italy 621.
Nonmetals:			
Diamonds:			
Diamond office—1,000 carats	1,413	1,158	All to United Kingdom.
Sierra Leone Selection Trust, Ltd.—do	632	(1)	
Total—do	2,045	1,158	
Mineral fuels:			
Petroleum, refinery products: [2]			
Gasoline, aviation—1,000 42-gallon barrels	2	4	All to bunker loadings.
Kerosine [3]—do	4	15	Do.
Distillate fuel oil—do	741	633	Do.
Residual fuel oil—do	1,376	1,284	Do.
Lubricating oils—do	2	1	Do.

[1] Production withheld until 1963.
[2] All are reexports.
[3] Includes jet fuels.

Metal and mineral imports fluctuate around 18 percent of total imports by value; in 1961 and 1962 they were, respectively, WA£6 million and WA£5.5 million. In each year petroleum products accounted for more than 64 percent of total value. Petroleum products were largely supplied by Venezuela and the Netherlands. In most other import commodity areas the United Kingdom led. The United States increased its exports to Sierra Leone in 1962 to US$4.3 million, including US$920,000 worth of mining and construction machinery and parts.

COMMODITY REVIEW

METALS

Bauxite.—Bauxite in significant quantity was first discovered in Sierra Leone early in 1960, by its Geological Survey. The deposit is in the Mokanji Hills in the Mayamba District. The bauxite is of good quality, both for high alumina content and low content of silica and iron. In March 1963 the Ministry of Lands, Mines and Labor announced discovery of another deposit in the Kpaka Chiefdom of Pujehun District, also by the Survey.

In 1962 SLOM obtained from the Government the right to mine the original discovery, and in 1963 SLOM obtained an option on the Kpaka Chiefdom deposit. Production from the original discovery began in 1963, and by the end of the year SLOM had exported nearly 20,000 metric tons—avering 55 percent Al_2O_3. Anticipated future output is about 100,000 tons annually.

Iron Ore.—The value of iron ore exports of Sierra Leone Development Co. (DELCO) in 1962 and 1963 was, respectively, WA£5.1 mil-

Digitized by Google

lion and WA£4.9 million. DELCO ore mineral is specularite. The principal product exported is a specularite concentrate containing about 65 percent iron. Under the trade name Ferromax DELCO also produces quantities of nearly pure specularite, largely for use as pigment. Both in 1961 and 1962 about 1,000 tons of Ferromax was exported, chiefly to West Germany.

DELCO had in progress a program to increase iron ore production by 40 percent to 2.8 million tons per year by the end of 1965. Projects under the program include deepening the ship channel to the port at Pepel, construction of a new ore-loading pier, improving the company railroad from mine to port, and acquisition of new ore cars and milling equipment.

Rutile.—At the end of 1963 the outlook was that the joint rutile project near Gbangbamg would reach production. In that case Pittsburgh Plate Glass Co. will be the U.S. company with the largest investment in Sierra Leone.

NONMETALS

Diamonds.—About 40-percent of the diamond found in Sierra Leone is gem diamond; and large diamonds (weighing 5 carats and more) comprise a significant part of total production.

Under an agreement reached in late 1962 between Sierra Leone Selection Trust, Ltd., (SLST) and the Government, half of the company output was to be sold to the Diamond Corp. (De Beers) and the other half to three U.S. companies. Pending the new agreement, SLST withheld 1962 production and that of the last 4 months of 1961 until early in 1963, when SLST exported nearly 700,000 carats valued at more than WA£6 million and representing 16 months production. The production of small operators, called diggers, must be sold exclusively to the Government Diamond Buying Office, operated by the Diamond Corp.

SLST.—Consolidated African Selection Trust, Ltd. (CAST), which controls SLST, has reported SLST production during the past 5 years as follows in carats (years ended June 30): 1959—640,000; 1960—702,384; 1961—796,715; 1962—715,808; and 1963—663,865.

CAST reported in part as follows regarding operations during the year ended June 30, 1963.

Profit was £4,271,000; £740,000 more than in 1962.

The decrease of 7 percent in quantity of diamonds produced reflected treatment of lower grade material in accord with grade of reserves. Gravel treated was 755,393 cubic yards. The policy of maintaining balanced working of deep deposits and shallow deposits was continued. As a result the ratio of overburden to gravel excavated increased; 3.5 cubic yards of overburden were removed for each cubic yard of gravel mined. This compared with 3.2 and 2.9 cubic yards, respectively, in the previous 2 years.

Prospecting and development continued in the Yengema and Tongo areas. Sinking the prospect shaft to examine kimberlite exposures in depth was begun. Experimental work continued with the small dredge installed earlier on the Bafi River. Results showed the dredge capable of recovering diamonds from the river bed. After minor

Digitized by Google

modifications, the dredge was expected to increase overall production to a small extent.

Digger Operations.—The numerous small producers, operated under the Government alluvial-diamond-mining scheme, which has become an important feature of the national economy. The scheme remained under the general supervision of the Assistant Chief Inspector of Mines stationed at Kenema. The area in which the scheme operated in 1962 was roughly 9,500 square miles (24,600 square kilometers). The Revolving Loan Fund, started in 1960 with a free grant of the U.S. Government, continued to be very popular—encouraging miners to use machinery, providing spare parts promptly, and making equipment available at reasonable prices.

Exports of digger production by the Diamond Office in 1962 and 1963 were, respectively, 1,158,000 carats valued at US$19.9 million and 649,000 carats valued at US$18.9 million. The value of exports in 1963 approached the 1962 value despite the sharp decline in volume, because purchases included large quantities of gem diamond for which the market was strong, permitting the Office to increase its buying price. According to the Report of the Department of Mines of Sierra Leone for 1961 (most recent year for which the data are available), 45.5 percent of the purchases of Diamond Office in 1961 were gem diamond. Further data from the report, revealing the significance of gem diamonds follows:

	Carats purchased	*Value WA£*	*Value per carat WA£*
Gem diamond	439,861	9,519,989	21.60
Industrial diamond	966,538	1,859,708	1.92

Barring significant new discovery, it appears that digger production will decline further as the richer and shallower deposits become exhausted. Such a development would seriously hurt the economy of the whole country because the earnings of diggers move directly into the economy, and diamonds provide the largest part of national cash income.[7]

The Mineral Industry of the Somali Republic

By Thomas G. Murdock [1]

THE Somali Republic, also known as Somalia, became independent on July 1, 1960; the northern region was formerly British Somaliland and the southern region, Italian Somaliland, which was a United Nations Trusteeship administered by Italy for 10 years prior to independence. Somalia's mineral resources are meager, and during recent years production has consisted of only a small quantity of salt evaporated from seawater; extensive undeveloped gypsum deposits are known and several other minerals occur in quantity, but adverse economic factors have not permitted their exploitation. Oil exploration was continued during 1963, but optimism regarding discovery prospects decreased following another unsuccessful year. Except in the petroleum sector there was little exploration activity although the results of previous work were reappraised and studied further. Data available on imports of metals and minerals are incomplete, but indications are that imports continued to be comparatively small for a country of 1.97 million inhabitants and consist mainly of petroleum refinery products and metals.

In 1962 the gross national product (GNP) was So Sh550 million (US$77 million).[2] The 1962 salt production was valued at about So Sh177,280; thus mineral production contributed only 0.03 percent to the GNP.

Data on employment in the recovery of salt are not available. Petroleum exploration companies in Somalia employed 588 workers, 80 percent of whom were Somali nationals.

GOVERNMENT POLICIES AND PROGRAMS

No new mining or petroleum legislation was reported in 1963. The Somali Republic encourages investments, especially in oil exploration, and grants concessions on a negotiated basis. At yearend negotiations toward an investment guarantee agreement with the United States, covering covertibility, expropriation, and war risk were nearing completion, and the agreement was expected to be signed early in 1964. A 5-year plan began in 1963, but little information on progress has become available; this plan provided for the exploitation of the gypsum deposits near Berbera port in the northern region.

SOURCE MATERIAL

This country review has been prepared almost exclusively from a Foreign Service Dispatch,[3] supplemented by an article [4] in the English press and articles in other technical journals.

PRODUCTION

Production has been reported for salt only in some years; it has been estimated for other years. Output was 4,000 metric tons in 1959, rising to an estimated 7,000 tons in 1960. For subsequent years it has remained at about 2,000 tons, although in 1962 the quantity was only an estimate. The decrease since 1960 was apparently due to decreased exports, although these have never been large. Small quantities of construction materials are produced, but no quantitative data are available.

TRADE

Somalia's exports of minerals and metals in 1962 were limited to 412 tons of sea salt, valued at So Sh43,000 (271 metric tons and So Sh31,170 in 1961). Principal 1962 destinations were Kenya 319 tons (So Sh33,010), Ethiopia 70 tons (So Sh7,520), and Saudi Arabia 8 tons (So Sh1,205). Salt exports in 1962 were only 0.02 percent of all exports. Available data on imports only show 1962 metal and mineral imports valued at So Sh21 million, 7 percent of all imports, and consisting of metals, So Sh7.6 million and petroleum refinery products, So Sh14 million. Comparable 1961 data are not available, except for petroleum refinery products which totaled So Sh11 million. Data on sources of 1962 imports are available only for the petroleum refinery products. Value of these imports by principal suppliers was—Iran, So Sh8.2 million; Saudi Arabia, So Sh2.7 million; Italy So Sh1.1 million; United States So Sh0.6 million; United Kingdom So Sh0.4 million.

TABLE 1.—Principal imports of metals and minerals

(Metric tons unless otherwise specified)

COMMODITY REVIEW

METALS

Iron Ore.—Earlier estimates of the undeveloped iron ore reserves at Bur Galan have been revised upward, to 400 million metric tons to a working depth of about 100 meters. Samples analyzed by the Mineral Resources Division had an average iron content of 37.8 percent. Although having a high silica content, the ore is free from other objectionable impurities; the average phosphorous content is just below the Bessemer limit and, therefore, concentrates produced would be of Bessemer grade. The ore is regarded as low- to medium-grade concentrating ore. The United Nations Special Fund agreed to undertake further investigations, including an aerial magnetometer survey and core drilling.

Manganese.—Further investigations were commenced on manganese silicate rocks at Hudiso, in view of renewed interest shown by United Kingdom mineral importers. The reserve of accessible ore was thought to be much less than earlier estimated.

Titanium.—No further information about the extent of the titanium-bearing black sands at the mouth of the Juba River in the southern region has become available.

Tin.—Cassiterite reserves at Dalan were estimated at only 53 long tons to a depth of 30 meters, based on a minimum grade of 0.3 percent metallic tin over a stopping width of 91 centimeters. Quartz veins, not yet exposed, might yield 80 tons more. Two Russian geologists examined the deposits and considered that the reserve estimate could be increased tenfold, based on their experience with similar U.S.S.R. occurrences. Also, they believed that the Dalan deposits could be worked if a suitable water supply was found. Small-scale mining of tin ore in Magiaian region has resulted in the export of about 16 long tons over the past decade.

NONMETALS

Feldspar.—Prospecting operations for potash feldspar continued to be concentrated on a large pegmatite dike in the Humbeli Range, previously worked for mica, beryl, and columbite, with a reserve of high-quality feldspar of about 7,500 metric tons. Smaller tonnages could be obtained from other pegmatites in the region. Development of the feldspar resources was not possible without the provision of adequate transportation facilities; plans have been made for these, but funds have not become available. Possibilities of the marketing feldspar and other minerals in the pegmatites were under investigation by a United Nations trade promotion specialist in the country.

Salt.—Somalia once had a large salt production from the solar evaporation of seawater. Prior to World War II the plant at Ras Hafun had an annual capacity of 300,000 tons; it has fallen into complete disuse and the small annual production continued to be from salt pans along the coast, mainly for domestic consumption and small exports to Saudi Arabia and neighboring African countries. Japanese firms reportedly showed interest in reviving the salt industry, but there were no concrete developments.

Digitized by Google

Sepiolite (Meerschaum).—Although no quantitative data are available indications are that small quantities of sepiolite may have been mined for local use. Large deposits are reported in the Bur region of the north, but there has been practically no commercial exploitation for export.

MINERAL FUELS

Petroleum.[5]—Sinclair Somal Corp. abandoned Brava well No. 1 at a depth of 381 meters; spudded late in 1962, this well was near the Indian Ocean coast about 200 kilometers southwest of Mogadiscio. Sinclair subsequently intensified seismic work and drilling of another wildcat was scheduled for 1964.

Mobile Petroleum Co. reported completion of three wells for stratigraphic correlation; known as Galcaio 1, 1A, and 2, these wells reached respective depths of 434, 680, and 2,134 meters. Other wells included Idone 1, 72 kilometers south of Galcaio, drilled to 2,134 meters, and Burti 1, at 314 kilometers southwest of Obbia and 169 kilometers inland, drilled to 2,137 meters. Mobile exploration had indicated an evaporite basin near the Somali-Ethiopian frontier; efforts were made to find porous zones in hard limestone downdip of the evaporites, but the company planned on discontinuing drilling early in 1964.

A small area held by an Italian firm, Mineraria Somala, in the northern part of the country was relinquished.

Since 1953 U.S. firms together with Gulf Oil Corp., which has also been active in the Somali Republic, spent the equivalent of about So Sh286 million in exploration. To date no commercial discoveries have resulted, although traces of oil and gas have been found in Coriolei. The Somali Republic Government has realized annually about So Sh2.14 million from its agreements with the companies on operations, tariffs, and foreign exchange transfers.

The Mineral Industry of the Republic of South Africa

By Thomas C. Denton [1]

THE REPUBLIC OF SOUTH AFRICA possesses large resources and is an important producer of a great variety of minerals and metals. The value of aggregate output in 1963 was about R1 billion.[2] In addition the Republic has an extensive and sophisticated mineral and metal processing and fabricating industry, such as exists nowhere else in Africa.

Gold continued to rank first among minerals produced in 1963. In 1962 gold production contributed 68 percent of the value of South African mineral production and, by volume, 67.5 percent of world gold production exclusive of Communist countries. Uranium was an important byproduct of gold mining. Coal has provided the energy base of the country. The aggregate reserve is large and far exceeds the measured coal reserve of the rest of Africa. The coal, together with abundant resources of iron ore and limestone, has been the basis for a domestic iron and steel industry with annual capacity 10 times that of any other African country.[3]

Important quantities of more than 40 additional minerals were produced. Included among these minerals were asbestos, diamond, antimony, chromite, copper, manganese, platinum, and vanadium. In fact, if adjacent South-West Africa were included with the Republic, virtually the only important minerals lacking would be petroleum, bauxite, potash, and molybdenum. South-West Africa has lead and zinc, which the Republic lacks. Search for petroleum continued in 1963. As a possible substitute for bauxite, high-aluminum clays are abundant in the country.

In the year ended June 30, 1963, the contribution of mining to the net domestic product (NDP) of the Republic was third after that of private manufacturing and the public sector. The NDP was estimated at R5,481 million,[4] to which mining contributed 13 percent; the public sector, 15 percent, and private manufacturing, 25.5 percent. In 1962 mining provided 14.6 percent.

---

[1] Africa specialist, Division of International Activities.

[2] Currency of the Republic of South Africa is the rand (R). One rand equals US$1.40. Effective May 31, 1961, the Union of South Africa, up to that time a member of the British Commonwealth of Nations, became the Republic of South Africa, and withdrew from the Commonwealth. Decimal currency was then adopted; the former South African Pound (SA£) was replaced by the rand, at the rate of SA£1 = R2.00.

[3] Southern Rhodesia and Egypt are the only other African countries with integrated iron and steel industries.

TABLE 1.—Contributions of South Africa to world supply of selected minerals in 1963

(Percent)

Commodity	World, exclusive of Communist countries	World, including Communist countries [1]
Gold	70.4	53.1
Chromium ore	33.5	19.5
Platinum-group metals	41.8	20.0
Antimony	37.4	20.1
Manganese ore	20.3	9.0
Vanadium	19.9	(2)
Uranium, U_3O_8	15.0	(2)
Diamond	13.0	11.9
Asbestos	10.3	6.4
Beryl	6.8	5.7
Coal, all grades	3.4	1.6
Fluorspar	3.2	2.5
Copper	1.4	1.2
Corundum	1.0	.6

[1] Most figures for Bloc production are estimates.
[2] Data not available.

Mining, including precious, ferrous, and nonferrous metal smelting and refining, is recognized to be the industry on which the country has basically depended. Largely this has resulted from gold mining. This industry consistently has been the largest single generator of national income, provider of foreign exchange, and employer of labor. In addition, its large requirements for machinery, supplies, and agricultural products (food and lodging are part of wages of African labor) have promoted and stimulated the domestic manufacturing and agricultural industries. Some salient statistics for South African mining industry in 1961, including gold mining, appear below:

Average number of persons at work	667,651
Salaries, wages, and allowances paid—million Rands	293
Value of stores and electric power consumed, million Rands:	
South African	290
Imported	33
Total	323

South Africa in 1963 had extensive facilities for smelting, refining, and manufacturing mineral and metal raw materials. The country, however, lacked facilities for primary smelting of lead and zinc and had only a small capacity for electrolytic copper and nickel production. The bulk of the industries were based on use of domestic raw materials. Existing facilities turned out iron and steel, ferroalloys, sulfuric acid, other acids, ammonia, explosives, superphosphates, cement, a variety of advanced chemicals, and tungsten metal and alloys. In addition, an oil-from-coal plant manufactured approximately one-sixth of South African gasoline requirements besides diesel and fuel oil and chemicals. Artificial diamond also was produced.

Lack of petroleum was by far the most serious mineral deficiency of South Africa; the petroleum refineries used imported crude oil. There were also plants turning out semimanufactures and manufactures of copper, lead and zinc, and aluminum which depended heavily or entirely on imported raw materials.

Digitized by Google

An important development in 1963 concerned an unusual mineral complex at Phalaborwa, Transvaal Province.[5]

The complex consists of a volcanic pipe about 7 square miles in area. Concentric, vertically dipping rings of ore in the complex include carbonatite (copper and iron), foskorite (iron, apatite, zircon, copper), pyroxenite (pyroxene, apatite, vermiculite), and syenite (potash and aluminum). Tantalum, vanadium, titanium, gold, and silver also occur.

Output from the complex in 1963 consisted of 163,000 metric tons of apatite for superphosphate manufacture, byproduct copper concentrate, and 77,000 tons of vermiculite. Through an R8 million expansion program, apatite production was to be trebled, to satisfy domestic requirements for raw phosphates. In addition, a 3-year program to cost R76 million had been started to exploit the large reserve of low-grade copper ore which had been developed in the complex during the past several years. Design capacity for copper is 73,600 metric tons of blister. Finally, a plant for manufacturing phosphoric acid and superphosphate was to be built near the apatite mine; the sulfuric acid for the superphosphate plant probably would be produced in an acid plant using flue gas from the smelter copper converters. Only about 20 percent of the machinery required for the project would have to be imported.

A new plant for mechanically loading ore into ships, built by the government-owned South African Railways and Harbors at Port Elizabeth, went into operation in April 1963. It cost R1.5 million and can load 1,360 tons per hour. Ore is weighed while it is being moved into the ship. The plant has several storage bins with aggregate capacity of 167,000 tons, making possible storage of several grades of iron ore and manganese ore for which the facility is chiefly intended.

The first full year of production from South Africa's Witwatersrand goldfield was 1887. British capital was principally involved. It soon became evident that large-scale operations requiring heavy capital investment were needed to exploit the field profitably. Many early companies failed, in part for lack of adequate capital. Ultimately most of the survivors came under control of a few strong financial groups, chiefly in London, which incorporated and became mining investment and mine-financing companies. Additional companies were incorporated later.

The companies are known in London and South Africa as Mining Houses or Groups. The Groups conduct extensive exploration and, when successful, float new operating companies. They hold sufficient shares in their operating companies to appoint directors and management and to act as secretaries and engineering and geological consultants to the sponsored companies. Other functions are to purchase supplies and to make loans to the companies of the Group. The Groups have gradually expanded and diversified their interests into other mineral commodities and into industry generally, in South Africa and to a lesser extent elsewhere in Africa and beyond the continent.

[5] Mining Journal (London). V. 261, July 26, 1963, p. 88.

Digitized by Google

The seven Groups listed as follows now control the great bulk of mining and metallurgical industry in South Africa exclusive of iron and steel and manufacture of oil from coal:

Anglo American Corp. of South Africa, Ltd., no significant American interest.
Anglo-Transvaal Consolidated Investment Co., Ltd.
General Mining and Finance Corp., Ltd.
Johannesburg Consolidated Investment Co., Ltd.
Rand Mines, Ltd.
The Consolidated Gold Fields of South Africa, Ltd.
Union Corp., Ltd.

Anglo American Corp., founded by the late Sir Ernest Oppenheimer, is by far the largest of the Groups and probably is the largest and most diversified mining-investment and mine-financing company in existence. In 1962 mines of the Anglo American Group in South Africa produced R212.9 million worth of gold, one-third of South African output. Diamond sales were more than R192 million. Coal mined by companies of the Group in South Africa and Southern Rhodesia, mostly in the former, was 17.3 million metric tons, representing 40 percent of the total coal production of Southern Africa and 38 percent of all Africa. Copper produced in Northern Rhodesia by mines of the Group was 60 percent of that output and 10 percent of that of the free world.

Private U.S. capital is substantially involved in South African mineral and petroleum refining industries. The overall value of the investment is not available. O'okiep Copper Co., Ltd., in Cape Province, largest copper producer in South Africa, is controlled by a U.S. company. This company and another U.S. company are committed to investment in a new large copper mining and smelting project at Phalaborwa, Transvaal Province. A large share of South Africa's chromite production is obtained from ore reserves owned by South African subsidiaries of U.S. companies. Mobil Refining Co. Southern Africa (Pty.), Ltd., a subsidiary of Socony Mobil Oil Co., has a petroleum refinery at Durban with daily crude capacity of 33,332 barrels. Many U.S. companies manufacturing excavating and other mining equipment have sales offices and personnel in South Africa, which in the aggregate represent substantial investment.

GOVERNMENT POLICIES AND PROGRAMS

During 1963 the South African Government intensified its drive toward maximum economic self-sufficiency. It was prepared to foster new industry, including mineral-transforming industry, by restricting imports through protective tariffs if such action was in the national interest. However, the government was not prepared to use the device to foster inefficient, high-cost operations.

SOURCE MATERIAL

Source material relating to the mineral economy of South Africa is extensive and authoritative. Some principal sources for this chapter are U.S. Foreign Service dispatches; "The Mineral Resources of the Union of South Africa," 1959; "Beerman's All Mining Yearbook," 1963; papers and discussions comprising the Transactions of the

Digitized by Google

Seventh Commonwealth Mining and Metallurgical Congress, 1961, Johannesburg; annual reports of the Department of Mines of the Republic of South Africa; miscellaneous technical and industrial trade journals; company reports; and personal observation. Statistical data are mainly from government sources, including the Quarterly Information Circular of the Department of Mines and the official foreign trade statistics of the Republic.

PRODUCTION

The South African Government does not report annual value of mineral and metal production. Approximate output value may be obtained by adding reported Department of Mines data on the values of (1) gold and silver production; (2) sales of domestic diamonds; (3) local sales of industrial minerals and of quarry products; and (4) value of exports of industrial minerals, including uranium. Besides uranium, industrial minerals include all minerals sold except gold, silver, diamonds, and quarry products. Local sales of industrial minerals include an item "other" which, it is understood, represents an estimate of value added by the transforming industry to mineral commodities sold locally in semimanufactured form, for example, ferroalloys. "Other" was 14.8 percent of the total value of local sales in 1962 and 17.5 percent in 1963.

TABLE 2.—Approximate value of mineral and metal production

(Thousand Rands) [1]

Commodity	1959	1960	1961	1962	1963
Gold production	500,272	536,019	574,900	636,582	686,312
Silver production	1,326	1,472	1,576	1,952	2,512
Diamond sales, domestic diamonds	31,317	33,852	38,370	36,483	36,638
Industrial minerals:					
Local sales [2]	87,165	94,522	101,748	104,356	116,204
Exports:					
Fissionable materials [3]	97,464	98,519	79,268	73,754	66,762
Other	68,738	89,472	94,680	94,911	99,369
Total	786,282	853,856	890,542	948,038	1,007,797
Quarry products, local sales	2,565	2,904	3,868	2,827	4,274
Grand total	788,847	856,760	894,410	950,865	1,012,071

[1] 1 Rand equals US$2.40. During 1958–60 values were reported officially in South African pounds, which have been converted to Rands at the rate: 1 South African pound equals 2 Rands.
[2] Includes an item identified as "other," which was reported as follows in thousand Rands: 1959, 13,792; 1960, 15,851; 1961, 17,346; 1962, 15,369; 1963, 20,456.
[3] Comprises uranium (U_3O_8) and, before 1962, relatively small quantities of monazite.

During the period 1959–63, the grand total of values reported by the Department of Mines increased steadily, reaching R1 billion in 1963. The uninterrupted improvement mostly resulted from a steady increase in gold production, which rose by 37 percent to a new record of R686.3 million in 1963. The values of other categories reported, either also increased or fluctuated only slightly during the period, except exports of uranium. Uranium exports were highest in 1960 at R98.5 million, declining to R66.8 million by 1963.

[1] Sales.
[3] Estimate.
[3] Data not available.
[4] Not reported the same as in 1959–62; total includes 1,246,000 metric tons of metallurgical grade ore, 62,000 tons of chemical grade ore, and 50,000 tons of manganiferous ore, containing 15 to 30 percent Mn and 20 to 35 percent Fe.
[5] Natural alloy of osmium, iridium, small quantities of other platinum-group metals, and gold; recovered by certain gold mines.
[6] Includes small quantities of cupreous pyrite.
[7] Dense rock containing up to 98.4 percent SiO_2; used in manufacture of silica refractories.
[8] Decorative material resulting from oxidation and silicification of crocidolite.
[9] A soft, easily worked dimension stone.
[10] Includes production from imported oil, domestic oil shale, and domestic coal.
[11] Includes Union Motor Spirit; a blend of 50 percent imported gasoline and 50 percent sugarcane alcohol.
[12] May include some residual fuel oil.

TRADE

The statistical territory of the Republic of South Africa extends beyond its political boundaries and includes the Territory of South-West Africa (mandated to South Africa by the former League of Nations) and the British High Commission Territories of Basutoland,

Digitized by Google

Bechuanaland Protectorate, and Swaziland. Hence items of external trade involving only the Republic are not precisely identifiable; this, however, applies mainly for imports. South Africa accounts for the great bulk of external trade of the whole statistical territory. In what follows South Africa is assumed to have taken all import items named. Exports named are known to have originated in South Africa, with minor exceptions.

While petroleum must be imported, South Africa has a favorable balance of trade in nonfuel minerals and in metals and semimanufactures of mineral origin. Net export values in 1961 and 1962 by category were approximately as follows:

	Value, million rands	
	1961	*1962*
Iron and steel[1]	15.8	24.6
Nonferrous metals	100.4	90.3
Nonmetallic minerals	146.0	124.8

[1] Includes iron ore and ferroalloys.

Net-import value of fuels for 1961 and 1962, were, respectively, R66.5 million and R65.7 million. Both in 1961 and 1962 imports of crude petroleum and petroleum products comprised nearly 50 percent of total imports. The decision of Kuwait to sever economic relations with South Africa was not expected to cause a crisis in oil supply but would be inconvenient.[6]

Excluding gold, the value of South African exports in 1962 of minerals, metals, and semimanufactures of mineral origin was about R340 million, including R73.7 million of uranium. The exports were 39 percent of total value of exports of domestic products of R867.4 million, excluding gold. Including R636.5 million of gold production, the mineral industry contributed 65 percent of total export earnings. In few countries of the world is the contribution of mineral industry to exports so large. While the value of exports, excluding gold, in 1962 was 6 percent less than in 1961, the increase in gold production was four times the decline.

The value of mineral exports to the United States in 1962 exclusive of iron and steel was about R19.1 million and somewhat higher than in 1961; decreases in chrome and manganese were more than offset by increases in asbestos and copper. Iron and steel exports to the United States included nearly 14,000 metric tons of ferromanganese and more than 43,000 tons of semimanufactures. Of total 1962 exports of iron ore and pig iron, Japan took, respectively, 82 percent and 52 percent.

TABLE 4.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	Total		Distribution, 1962 [1]	
	1961	1962	United States	Other principal destinations
Metals:				
Antimony	16,553	18,349	[2] 5,461	
Beryllium	65	318	309	Japan 9.
Bismuth ore	----------	1	----------	Argentina 1.
Chromite ore:				
44 percent and less Cr_2O_3	[4] 450,712	[4] 341,121	(3)	
More than 44 to 48 percent Cr_2O_3.	[4] 405,860	[4] 394,634	(3)	
More than 48 percent Cr_2O_3	[4] 2,115	[4] 2,149	(3)	
Total	[4] 858,687	[4] 737,904	541,853	West Germany 94,686; United Kingdom 57,102; Netherlands 18,221.
Copper:				
Contained in concentrates	242	43	----------	All to Japan.
Fire refined and blister	49,931	43,476	18,486	Belgium 9,753; Italy 5,801; West Germany 3,607.
Gold:				
Contained in troy ounces ores and concentrates.	640	1,393	(3)	
Bullion ----------do	19,505,000	19,390,000	(3)	
Iron and steel:				
Iron ore	556,028	754,312	----------	Japan 619,110; Austria 50,833; France 35,941.
Pig iron [5]	248,054	216,006	4,614	Japan 111,785; Netherland 48,033; Italy 40,427.
Ferroalloys:				
Ferromanganese [5]	132,303	78,687	13,773	United Kingdom 22,014; Canada 10,224; Italy 7,507.
Other [5]	28,752	15,374	1,647	Australia 3,141; United Kingdom 2,919; Netherlands 1,387; Belgium, 1,337.
Steel ingots and equivalent primary forms.	17,545	30,958	2,540	United Kingdom, 14,288; Argentina, 5,013; Uruguay, 4,999; Pakistan, 3,575.
Semimanufactures:				
Angles, shapes and sections. [6]	6,930	8,282	(6)	(6).
Bars and rods [5]	41,986	62,438	(6)	(6).
Drill and tool steel [5]	90	82	(6)	(6).
Plate and sheet:				
Plain [5]	23,334	55,061	(6)	(6).
Galvanized [5]	30,090	28,512	(6)	(6).
Undifferentiated [5]	34,784	105,372	(6)	(6).
Pipe [5]	11,540	10,453	(6)	(6).
Pipefittings [5]	2,011	2,221	(6)	(6).
Rails [5]	17,745	22,768	(6)	(6).
Total	168,510	295,189	43,101	Federation of Rhodesia and Nyasaland 76,555; United Kingdom 71,972; Italy 48,736.
Manganese:				
Ore:				
40 percent and less contained manganese.	[4] 576,809	[4] 546,618	(3)	
More than 40 to 45 percent manganese.	[4] 46,900	[4] 145,689	(3)	
More than 45 to 48 percent manganese.	[4] 119,738	[4] 145,458	(3)	
More than 48 percent manganese.	[4] 7,269	[4] 22,427	(3)	
Total	[4] 750,716	[4] 860,192	161,349	France 223,943; West Germany 111,599; United Kingdom 94,548 Japan 87,353.
Electrolytic metal [5]	----------	3,661	517	United Kingdom 658; Sweden 541; Netherlands 437.
Monazite	----------	8,114	(3)	
Platinum group metals. troy ounces	[7] 350,000	[7] 300,000	----------	All to United Kingdom.
Silver ----------do	1,629,321	2,120,592	1,360,686	United Kingdom 679,993; Japan 79,913.
Tantalite	1	10	5	Netherlands 5.

TABLE 4.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	Total		Distribution, 1962 [1]	
	1961	1962	United States	Other principal destinations
Metals—Continued				
Tin concentrates—long tons	1,394	1,422	----------	United Kingdom 1,296.
Titanium:				
Ilmenite	81,785	60,308	(3)	
Rutile	1,904	294	(3)	
Uranium, U_3O_8 [5]	5,188	4,183	[2] 4,262	
Vanadium:				
Fused oxide	2,294	1,440	(3)	
Ammonium vanadate	(3)	47	(3)	
Zircon concentrates and flour	5,325	6,045	(3)	
Scrap and old metal [5]	14,834	5,880	10	Japan 5,387; Italy 257; Netherlands 125.
Nonmetals:				
Andalusite and sillimanite	93,107	46,256	242	United Kingdom 16,006; Japan 12,006; West Germany 11,357.
Asbestos:				
Amosite	61,564	63,193	17,966	United Kingdom 19,164; Australia 5,624; Italy 5,190.
Crysotile	22,765	24,982	----------	Spain 5,565; Australia 4,298; Italy 3,247.
Cape blue	68,675	68,135	8,741	Italy 8,565; France 6,700; Japan 6,247; West Germany 4,843.
Transvaal blue	10,909	10,765	3,071	Japan 1,361; United Kingdom 1,239; Czechoslovakia 963.
Tremolite	4	----------	----------	
Total	163,917	167,075	29,778	
Cement:				
Building [5]	4,006	16,018	----------	(6).
Fire and furnace [5]	4,322	3,908	----------	(6).
Other [5]	1,061	691	----------	(6).
Total [5]	9,389	20,617	----------	Mauritius 14,189; Federation of Rhodesia and Nyasaland 4,614; Republic of the Congo (Léopoldville) 903.
Corundum, crystal	144	317	(3)	
Diamond:				
South African production: [5]				
Rough, uncut [5]—carats	1,818,244	1,743,794	51,972	United Kingdom 1,363,198; Belgium 235,749; Netherlands 63,001.
Unmounted, do—cut and polished. [5]	138,718	132,968	25,401	Belgium 58,310; Hong Kong 28,160; United Kingdom 11,318.
Manufactured [5]—do	----------	998,519	50,095	Ireland 899,783; Federation of Rhodesia and Nyasaland 30,744; France 16,491.
Mixed origin, rough, do—uncut. [5] [10]	19,226,908	16,644,518	4,114,317	United Kingdom 11,189,396; Ireland 1,066,712; Federation of Rhodesia and Nyasaland 96,935.
Total [5]	21,183,870	19,519,799	4,241,785	
Emerald crystals—kilograms	546	162	----------	All to United Kingdom.
Feldspar	4,851	7,805	----------	United Kingdom 3,703; Netherlands 1,558; West Germany 1,310.
Flint clay	78,207	73,662	----------	West Germany 35,207; Japan 28,071; United Kingdom 7,970.
Fluorspar:				
Acid grade	526	2,123	----------	Japan 762; Netherlands 722; Australia 379.
Ceramic grade	7,904	26,349	----------	Japan 12,834; Canada 9,902; Australia 749.
Metallurgical grade	69,265	42,458	----------	Netherlands 14,421; Japan 11,927; Sweden 5,271.
Total	77,695	70,930	----------	
Graphite	19	18	----------	All to Singapore.

TABLE 4.—Exports of metals and minerals—Continued
(Metric tons unless otherwise specified)

Commodity	Total		Distribution, 1962 [1]	
	1961	1962	United States	Other principal destinations
Nonmetals—Continued				
Gypsum	22,155	14,524	----------	Federation of Rhodesia and Nyasaland 13,152.
Lime and limestone	12,777	11,386	----------	Federation of Rhodesia and Nyasaland 9,485; Mozambique 1,451.
Lithium minerals	51	931	----------	All to United Kingdom.
Magnesite	----------	10	----------	All to Italy.
Marble	----------	7	[3]	
Mica	1,324	795	----------	West Germany 247; United Kingdom 202; France 165.
Mineral pigments	3,048	2,519	97	United Kingdom 2,242; Australia 111; Netherlands 27.
Pyrites, sulfur content	2,282	4,488	----------	Federation of Rhodesia and Nyasaland 2,321; South-West Africa 2,167.
Salt	19,538	25,122	----------	Federation of Rhodesia and Nyasaland 22,565; Swaziland 1,901; Bechuanaland 418.
Silcrete	----------	122	----------	All to United Kingdom.
Silica	518	----------	----------	
Talc	14	1	----------	All to Mozambique.
Tiger's eye	5	57	[3]	
Vermiculite	64,467	69,759	10,975	United Kingdom 22,813; Italy 10,912; West Germany 7,090.
Wonderstone	655	1,036	1,011	United Kingdom 25.
Mineral fuels:				
Coal:				
Anthracite [5]	309,329	524,853	----------	Italy 152,576; Japan 75,950; France 67,952; Netherlands 66,508; Argentina 60,851; Kenya 41,919.
Other [5]	746,877	1,120,549	----------	Mozambique 425,484; Burma 302,514; Pakistan 176,375; Ceylon 166,341.
Coke [5]	9,125	13,811	----------	Burma 10,965; Japan 1,508; Mozambique 660.
Petroleum refinery products:				
Gasoline—thousand barrels	220	212	----------	Republic of South Africa bunker loadings 188; South-West Africa bunker loadings, 24.
Kerosine—do	559	444	----------	Republic of South Africa bunker loadings 427; South-West Africa bunker loadings, 16.
Diesel oil—do	574	584	----------	Republic of South Africa bunker loadings 567; South-West Africa bunker loadings, 16.
Residual fuel oil—do	2,851	8,846	----------	Republic of South Africa bunker loadings 2,844.
Asphalt and bitumen	334	266	----------	Federation of Rhodesia and Nyasaland 86; Mozambique 34

[1] For most commodities, only partial distribution is given, with minor recipients omitted (except the United States when it falls in that category).
[2] United States imports.
[3] Data not available.
[4] Data by grade are provisional figures subject to change and do not add to totals reported in source in the tabulation of exports by destination. Totals for exports by destination, not given by grade are as follows: Chrome ore; 1961, 841,464 tons; 1962, 754,539 tons; manganese ore: 1961, 754,906 tons; 1962, 862,730 tons.
[5] Data from Foreign Trade Statistics, v. 2, Dept. Customs and Excise, Republic of South Africa. Includes exports for High Commission Territories of Basutoland and Swaziland, Bechuanaland Protectorate, and the Territory of South-West Africa.
[6] See distribution of total.
[7] Estimate.
[8] Reported as "Prescribed material under The Atomic Energy Act."
[9] Included with fused oxide.
[10] Includes an undisclosed quantity of South African production together with diamonds produced elsewhere in Africa and shipped to the Republic of South Africa for sorting and subsequent reexport. About 80 percent of the quantity reported is crushing bort from the Republic of the Congo (Léopoldville).

Source: Compiled from Quarterly Information Circular, "Minerals," Department of Mines, Republic of South Africa; this publication lists separately exports from the Republic of South Africa; the High Commission Territories of Basutoland, Swaziland, and the Bechuanaland Protectorate; and the Territory of South-West Africa. These areas are not separated from the Republic of South Africa in Foreign Trade Statistics, Volume 2, Department of Customs and Excise, Republic of South Africa, which has been used to supplement "Minerals" for commodities not listed in the latter publication. Data from "Minerals," however, do not represent officially recorded exports, as data are furnished by producers on intended disposal of output, and thus may differ from actual customs returns.

Digitized by Google

Imports in 1962 in general followed the pattern of recent years. Middle East countries furnished the bulk of petroleum and petroleum fuels. Copper and zinc came largely from Northern Rhodesia and the Republic of the Congo (Léopoldville). Imports from the United States comprised chiefly aluminum ingot and semimanufactures, and steel semimanufactures. Northern Rhodesia furnished about 72 percent of imports of lead in primary forms. Mainland China and U.S.S.R. supplied 86 percent of imports of antimony metal. Mercury imports in part originated in U.S.S.R. and Yugoslavia.

TABLE 5.—Imports of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1961	1962	Sources, 1962	
			United States	Principal imports from other countries
Metals:				
Aluminum:				
Ingots and equivalent forms [2]	10,362	14,023	573	Canada 13,301; France 146 United Kingdom 3.
Semimanufactures [3]	1,785	2,718	767	West Germany 449; France 431; Belgium 411.
Antimony, crude	161	267	--------	Mainland China 163; USSR 67; Yugoslavia 25.
Copper:				
Ingots and equivalent forms	23,316	24,965	18	Federation of Rhodesia and Nyasaland 18,914; Republic of the Congo (Léopoldville) 5,981.
Semimanufactures	627	[4] 1,143	4	United Kingdom 712; Belgium 249; Italy 118.
Copper alloys:				
Ingots and equivalent forms	71	39	5	United Kingdom 20; Netherlands 8.
Semimanufactures	577	[4] 815	(5)	West Germany 369; Italy 221; United Kingdom 156.
Iron and steel:				
Pig iron, steel ingots and equivalent forms.	312	151	--------	United Kingdom 148; West Germany 3.
Ferroalloys:				
Ferromanganese	2	11	--------	Sweden 6.
Ferrosilicon	455	460	4	West Germany 425; Sweden 19; France 7.
Other	383	412	(5)	Federation of Rhodesia and Nyasaland 227; USSR 124; Belgium 24.
Semimanufactures:				
Bars, rods, profiles and sections.	6,389	6,187	103	United Kingdom 4,259; Belgium 1,136; Sweden 274.
Plate, sheet, strip, and hoop, uncoated.	7,921	8,719	1,189	United Kingdom 3,519; Sweden 1,672; Japan 1,203.
Plate and sheet, coated with tin.	66,377	61,774	592	United Kingdom 49,300; Canada 6,566; France 3,821.
Plate and sheet, other coated.	562	853	108	United Kingdom 565; West Germany 61; Japan 57.
Cast pipe and fittings	1,204	[4] 625	--------	United Kingdom 617; Federation of Rhodesia and Nyasaland 8.
Wrought pipe and fittings	11,479	[4] 7,991	32	United Kingdom 5,958; Italy 556; Belgium 513.
Other tubes and pipes	987	2,044	184	United Kingdom 1,269; Sweden 415; Netherlands 71.
Rails, sleepers, and rail accessories.	404	2,068	20	United Kingdom 1,727; Federation of Rhodesia and Nyasaland 34; West Germany 13.
Tool and drill steel	1,562	1,488	6	United Kingdom 1,046; Sweden 208; West Germany 125.
Rough castings	119	154	3	United Kingdom 127; Federation of Rhodesia and Nyasaland 9; West Germany 6.
Total	97,004	91,903	--------

TABLE 5.—Imports of metals and minerals [1]—Continued
(Metric tons unless otherwise specified)

Commodity	1961	1962	Sources, 1962	
			United States	Principal imports from other countries
Metals—Continued				
Lead:				
Ingot and equivalent forms	12,174	13,646	(5)	Federation of Rhodesia and Nyasaland 9,810; Australia 2,646; Mexico 531.
Semimanufactures	27	76	8	Federation of Rhodesia and Nyasaland 29; Belgium 20; Netherlands 13.
Mercury—76-pound flasks	593	952	1	Italy 308; United Kingdom 227; USSR 167; Yugoslavia 130.
Platinum—troy ounces	845	2,441	-------	United Kingdom 2,440; West Germany 1.
Silver bullion—do	52,000	-------	-------	
Tin:				
Ingots and equiv- long tons alent primary forms.	670	504	-------	Federation of Rhodesia and Nyasaland 504.
Semimanufactures—do	3	1	(5)	United Kingdom 1.
Zinc:				
Ingots and equivalent forms	22,958	27,095	(5)	Federation of Rhodesia and Nyasaland, 23,228; Republic of the Congo (Léopoldville) 3,807.
Fume dust and shavings	5	59	-------	Federation of Rhodesia and Nyasaland 40; United Kingdom 19.
Semimanufactures	164	200	27	United Kingdom 150; Belgium 10; West Germany 10.
Solder and brazing alloys	207	125	-------	United Kingdom 85; Japan 28; Sweden 7.
Scrap and old metal	8,516	18,268	66	Federation of Rhodesia and Nyasaland 10,766; Republic of the Congo (Léopoldville) 1,755; United Kingdom 1,740.
Miscellaneous crude metals and ores.	76,428	39,578	302	Federation of Rhodesia and Nyasaland 31,540; Mozambique 4,609; Surinam 2,712.
Other metals	392	514	27	United Kingdom 291; Federation of Rhodesia and Nyasaland 88; Canada 62.
Pipe fittings of various metals [4]	-------	1,582	139	United Kingdom 956; West Germany 381; Sweden 51.
Nonmetals:				
Abrasives:				
Emery	38	89	3	Netherlands 56; United Kingdom 30.
Pumice	80	110	(5)	Italy 66; New Zealand 41.
Barite	1,220	2,115	27	West Germany 1,015; Federation of Rhodesia and Nyasaland 941; Netherlands 73.
Borax	2,017	1,706	1,701	United Kingdom 5.
Cement	11,266	9,422	902	United Kingdom 6,584; West Germany 825; Denmark 477.
Clays:				
Cornish stone, kaolin and china clay.	3,975	4,469	1,361	United Kingdom 2,441; West Germany 667.
Fire clay	1,953	1,730	1,460	United Kingdom 248; West Germany 21.
Diamond, rough:				
Of mixed African origin. carats	541,139	1,035,117	65	United Kingdom 970,946; Netherlands 50,457; Federation of Rhodesia and Nyasaland 3,984.
Other—do	16,580,677	15,011,709	-------	Republic of the Congo (Léopoldville) 14,569,958; Tanganyika 321,601; Angola 92,271.
Diatomaceous earth	2,548	2,425	1,971	West Germany 270; Kenya 76; France 53.
Fertilizer and fertilizer raw materials:				
Ammonium nitrate	29,668	19,674	-------	West Germany 12,319; Netherlands 4,842; Belgium 1,369.
Basic slag, Thomas	52,050	44,759	-------	Belgium, 44,759.
Phosphate rock	375,194	451,897	-------	Morocco 346,994; Tunisia 71,077; Togo 11,517.

(Metric tons unless otherwise specified)

Commodity	1961	1962	Sources, 1962	
			United States	Principal imports from other countries
Nonmetals—Continued				
Fertilizer and fertilizer raw materials—Continued				
Superphosphate	2,704	6,495	----	Federation of Rhodesia and Nyasaland 3,515; Netherlands 1,941; Italy 812.
Potash	66,229	81,597	12,896	West Germany 31,783; France 27,717; Israel 8,574.
Fuller's earth	757	994	405	United Kingdom 584; West Germany 5.
Graphite	289	567	174	United Kingdom 300; Norway 58; Japan 18.
Gypsum, including plaster of paris	2,078	2,444	19	West Germany 1,762; United Kingdom 573; Italy 69.
Mica	28	29	([5])	United Kingdom 18; India 3; West Germany 3.
Silica	903	582	345	West Germany 187; United Kingdom 30; France 15.
Salt	3,054	2,321	71	United Kingdom 1,924; Netherlands, 315; Federation of Rhodesia and Nyasaland 2.
Sulfur	113,146	118,338	46,935	Mexico 71,010; France 163; West Germany 121.
Other earths and clays	997	93	11	USSR 40; Denmark 39; United Kingdom 2.
Mineral fuels:				
Coal	([6])	29	----	([6]).
Coke	([6])	([6])	----	([6]).
Petroleum:				
Crude 1,000 42-gallon barrels	11,092	12,095	----	Iran 11,325; Iraq 555; Bahrein 192.
Refinery products:				
Gasoline ---do	10,257	10,424	----	Iran 4,208; Aden 2,891; Bahrein 2,416.
Naphtha, 1,000 42-gallon barrels	414	415	73	Iran 317; Indonesia 11; Iraq 8.
benzine and white spirit.				
Kerosine ---do	3,164	3,036	([7])	Iran 1,742; Bahrein 628; Aden 514.
Distillate fuel oils ---do	4,453	4,795	([7])	Iran 1,893; Saudi Arabia 1,130; Australia 965.
Residual fuel oil ---do	1,429	1,567	----	Bahrein 667; Iran 554; Aden 203.
Lubricating oil ---do	1,075	1,261	570	Netherlands Antilles 263; United Kingdom 218; Venezuela 181.
Pavement oil ---do	14	2	----	Canary Islands 1.
Other [8] ---do	41	37	8	United Kingdom 14; West Germany 9; Netherlands 2.
Bitumen	35,539	31,577	14,619	British West Indies 13,756 Netherlands 1,661; United Kingdom 804.

[1] Includes imports for British High Commission Territories of Basutoland, Swaziland, and the Bechuanaland Protectorate, and for South West Africa.
[2] Includes ingots, pigs, blocks, and cast bars and rods; excludes powder, all rolled products, and most castings in special shapes.
[3] Includes rolling-mill products.
[4] Pipe fittings of copper, copper alloys, iron, and steel were reported separately in 1961 and are included under the appropriate metal; these items were groupedi n 1962 official statistics and are thus not separable, but included under the general category of pipe fittings.
[5] Less than 0.5 ton.
[6] Data not available.
[7] Less than 500 barrels.
[8] Includes brake fluid, insulating oil, tar, and creosote.

COMMODITY REVIEW

METALS

Antimony.—As for many years past, the entire antimony production of South Africa in 1963 was by Consolidated Murchison (TVL) Goldfields and Development Co., Ltd., from a property in the Pietersburg District of Transvaal Province. The ore mineral is stibnite, with which appreciable gold is associated. The ore occurs in lenses in steep-dipping veins ranging in width from a few centimeters to 6 meters. Cobbed ore and concentrates were produced, virtually exclusively for export. The bulk of exports go to the United Kingdom and the United States. Twenty-three percent of U.S. general imports of antimony in 1963 originated in South Africa.

In 1963 Murchison milled approximately 163,500 metric tons of ore, 14.6 percent more than in 1962. Combined output of concentrates and cobbed ore averaging 59.98 percent antimony was 18,621 tons. Ore reserves at the end of 1963 minable for combined antimony and gold at their respective prices on December 31 totaled almost 310,000 tons. Exploration by surface and underground diamond drilling continued. The additional information thus obtained sustained the view that mining operations should continue for at least 8 years, assuming the present price for antimony and present production costs.

Toward the end of the year additional equipment was being installed to bring annual milling capacity to 180,000 tons by June 1964. The move resulted from a firming of antimony prices with withdrawal of supplies from mainland China.[7]

Chromium.—The ultimate reserve of chromite in South Africa is considered by many chromite authorities to be the largest in the world. Reportedly, the presently minable reserve is at least 200 million tons.[8] Two or more companies owned or controlled in the United States retained ownership of a large part of the chromite reserve and operated large holdings.

The ore occurs principally in two belts in the Bushveld Igneous Complex in Transvaal Province. The western belt is about 160 kilometers long, and the eastern belt about 120 kilometers long. In both belts the ore occurs as multiple gently dipping (10–25 degrees) layers or seams of which three groups are recognized, known as the lower, middle and upper groups. The width of the layers ranges from a few centimeters to 2 meters. By using the resuing method of stoping, seams as narrow as 24 centimeters can be profitably mined when chromite prices are good.

In the eastern (Lydenburg) belt only No. 5 seam of the lower group has been extensively exploited. It is 1.5 to 1.8 meters thick but is stoped across only 107 to 137 centimeters, which contains most of the chromite. The seam is traceable for 88.5 kilometers.

In the western (Rustenburg) belt several mines generally are operated in each of the three groups of seams. Most seams are much narrower than No. 5 of the eastern belt.

Digitized by Google

Most of the ore produced is medium to low grade with a chromium to iron ratio of about 1.56:1.[9] The bulk of output has comprised chemical-grade ore, but metallurgical grade and refractory grade also have been produced. The Republic is the leading world producer of chemical-grade ore; officially, production has not been recorded on the basis of use but according to Cr_2O_3 content.

Most South African chromite continued to be exported, although domestic consumption was increasing. In general about 75 percent of total exports have gone to the United States. For years South Africa has furnished virtually the entire U.S. supply of chemical grade chromite.

With respect to domestic consumption, local sales of chromite in 1963 totaled nearly 82,000 metric tons, more than 68 percent greater than in 1959. While the bulk of consumption has been in ferrochromium manufacture, chromite refractories and small quantities of chromium salts also have been produced. Ferrochromium capacity is being enlarged with a view to increasing sales abroad. Capacity in 1961 was estimated at 10,000 tons, whereas capacity in 1965 was projected for as much as 67,000 tons, distributed as follows:[10]

	Capacity, metric tons	
Company:	1961	Projected for 1965
African Metals Corp. including ferrometals	[1] 10,000	[1] 12,000
RMB Alloy's (Pty.) Ltd. (Rand Mines and Blelock, Ltd.)	Nil	20,000
Transalloys (Pty.) Ltd	Nil	15,000–20,000
Palmiet Chrome Mines, Ltd	Nil	10,000
Rand Carbide, Ltd	Nil	5,000
Total	10,000	62,000–67,000

[1] Estimate.

In 1963 the plant of Transalloys, at Witbank in the Transvaal, was being constructed. It will manufacture ferrochromium, using a process by which low cr: fe ratio ores can be used to produce a low-carbon product with high-chromium content.

Exclusive of ferromanganese, South African exports of ferroalloys in 1961 and 1962 were, respectively, nearly 29,000 metric tons and more than 15,000 tons, mostly ferrochromium. United States imports for consumption of South African ferrochromium were over 1,000 tons in each of those years.

Copper.—South African mine output of copper regularly has exceeded domestic needs for primary copper. But the country has only a small capacity for electrolytic copper refining, and the bulk of copper mined is exported. Hence refined copper must be imported in quantities that cost substantial foreign exchange. Imports in 1961 of copper in primary forms were valued at nearly R10 million. In a report on South African minerals potential issued in June 1963, the National Resources Development Council recommended consideration of an electrolytic refinery.

Imports of copper in primary forms mostly originated in Northern Rhodesia and Republic of the Congo (Léopoldville). Exports com-

[9] In 1962 ore with a high chromium to iron ratio was discovered; its importance is still unknown.
[10] Metal Bulletin (London). Oct. 30, 1962, p. 1.

Digitized by Google

prised blister and fire-refined copper and small quantities of concentrates, of which Japan has become the largest buyer. In 1962 more than 43 percent of combined exports of blister and fire-refined copper went to the United States. South Africa has generally consumed less than 800 metric tons of fire-refined copper annually.

There were two important, widely separated copper operations in 1963, and a third area was being developed. The active camps were the Messina in northern Transvaal Province near the Southern Rhodesia border and Nababeep in Namaqualand, Cape Province. The new project was at Phalaborwa, Transvaal Province.

The Messina field was exploited by Messina (Transvaal) Development Co., Ltd., which produced exceptionally pure fire-refined copper. Output in 1962 was nearly 11,000 metric tons. As of September 30, 1962, Messina reported ore reserves totaling 6,256,000 tons, assaying 1.53 percent Cu. Messina also has copper mines and a smelter in Southern Rhodesia.

In the Nababeep area the producer was O'okiep Copper Co., Ltd. (American controlled), which mined several deposits and produced blister copper, averaging more than 99 percent copper. Output in 1962 was more than 35,000 metric tons. In January 1963 the new O'okiep mill at Carolusburg was brought into production at an initial rate of 36,250 tons of ore per month. In July the monthly rate was increased to 72,500 tons by installing a new rodmill and moving certain equipment to Carolusburg from the East O'okiep concentrator.[11] The aggregate measured reserve of oxide and sulfide ore in various company deposits as of June 30, 1962, was about 25.5 million tons, averaging 2.07 percent copper.

Expected to be in production by 1966, the new project at Phalaborwa is a bold mining venture, which will cost about R75 million. The operating company is Palabora Mining Company, in which is South African, British, American, Canadian, and German capital on either or both an equity and a loan basis. The project consists of equipping for open-pit mining a large low-grade deposit, averaging 0.7 percent copper, and building a concentrator and a smelter nearby. The capacities of the facilities will be, respectively, approximately 30,000 metric tons of ore per day and 72,500 tons of blister copper per year. Ore reserves on which the venture is based are estimated at 286 million tons to an open-pit depth of 394 meters. Two favorable aspects of the project are that the stripping ratio for mining will be 1:1 and that a substantial tonnage of byproduct magnetite may be produced for local sale.

Another copper development was that the apatite producer in the Phalaborwa area, Phosphate Development Corporation (Pty.), Ltd., agreed to export to Japan annually about 17,000 tons of copper concentrate worth more than R2 million. The first shipment went forward via Lourenco Marques, Mozambique, early in November 1963.

Gold.—South Africa established new records for gold in 1963 for both production and working profit of the gold mining industry. Production was 27.43 million ounces. Estimated working profit was

[11] South African Mining and Engineering Journal. Jan. 3, 1964, p. 5.

Digitized by Google

R313 million. The profit was 7.9 percent greater than in 1962 and 18.5 percent greater than in 1961.[12]

The volume of gold mined in 1963 was about 70 percent of free world gold production, compared to 67.5 percent in 1962. Gold production has increased each year since 1952, when the country produced 11.8 million ounces.

Geology.—More than 99 percent of South African gold production has come from certain gold-bearing conglomerates (locally called reefs) of the Witwatersrand sedimentary system discovered in 1886. In certain ore bodies of the Witwatersrand (Rand) gold-bearing conglomerates, uranium is associated with gold, and the Rand conglomerates have been the source of all uranium the country has produced. In addition, some of the gold ore bodies contain sufficient pyrite for byproduct pyrite concentrates to be produced. These concentrates have been the major domestic raw material for sulfuric acid manufacture. Another byproduct of certain gold mines has been osmiridium, a natural alloy of osmium and iridium.

The Rand system comprises ancient sediments resting on an irregularly eroded granite floor. The present structure of the sediments is that of a main, apparently completely closed, roughly eliptical basin trending northeast, and what is probably a smaller basin, a short distance southeast of the northeast end of the main basin. The lengths of the axes of the main basin are roughly 256 kilometers and 96 kilometers. The northwest rim of the basin runs through Johannesburg, where it outcrops near the initial gold discovery. The remainder of the rim, mostly buried by younger, flat sediments, is partly in Orange Free State Province.

The sediments comprise two divisions. The Lower Division, resting on the granite floor, is about 4,600 meters thick and is mostly quartzites, minor shale, and conglomerate beds. The Upper Division is about 2,700 meters thick. It consists of quartzites, many conglomerate beds, and the argillaceous Kimberley shale bed. This Upper Division contains most of the gold-bearing conglomerates rich enough to be exploited. It is also the source of most or all of the associated uranium.

The following Reef horizons are or have been mined for gold, with or without byproduct uranium:[13]

Upper Division, from near bottom toward top:

- **Main Reef group, including Main Reef, Main Reef Leader, South Reef, and Carbon Leader, etc.**
- **Bird, Basal, and Vaal Reefs.**
- **Kimberley Reefs.**
- **Elsburg Reefs.**

Lower Division, from bottom toward top:

- **Domion Reef.**
- **Government Reef.**

The reefs are narrow. True widths range from 20 centimeters to 152 centimeters. Dips rarely are steeper than 35 degrees and in depth become progressively flatter.

[13] Seventh Commonwealth Mining and Metallurgical Congress. Transactions, 1961, v. 2, pp. 489–592. Map accompanying paper by R. Borchers.

Digitized by Google

Minable stretches of reef have been found at widely spaced intervals along the exposed or more generally buried rim of the basin. Beginning at Johannesburg and proceeding southwest around the rim, major Rand goldfields are known as Central Rand, West Rand, Far West Rand, Klerksdorp, Orange Free State, and East Rand. The mining area of the separate basin is called the Evander (formerly Kinross) area.

In 1962, in the Rand goldfields, there were 55 mines producing gold, several also produced byproduct uranium. In addition, 5 mines were primarily uranium producers, having byproduct gold production. The gold-mining companies, as well as major coal-mining companies in South Africa belong to an efficient, highly organized producers association called the Transvaal and Orange Free State Chamber of Mines. The Chamber issues annually a highly informative annual report; that for 1962 was its seventy-third.

Salient statistics of the gold-mining industry, exclusive of mines primarily producing uranium, including tons of ore milled, gold and uranium produced, and grade of ore are reproduced in table 6. The total volume of ore milled in 1962, including that milled by primary uranium producers, was nearly 68.5 million metric tons. For primarily gold producers, gold recovery per short ton ranged from 0.177 troy ounces by Consolidated Main Reef to 0.99 ounces for West Driefontein.

Sources: 1959–62, Annual Reports of the Transvaal and Orange Free State Chamber of Mines; 1963, Annual Mineral Industries Report for 1963 of the U.S. Consulate General, Johannesburg (Johannesburg Airgram A–7, July 7, 1964).

Refining.—The dore (unrefined) bullion produced by mines in 1963 was refined by a single gold refinery as in the past. This is Rand Refinery, Ltd., largest gold refinery in the world, which is owned by the major gold-mining companies. The refinery reputation for accuracy and uniformity of product is such that refined gold bullion shipped to the Bank of England is not remelted and sampled upon arrival but is accepted for fineness on the Rand Refinery certification.

Principal developments.—Western Deep Levels, which began milling in 1962, by late 1963 had increased quantity of ore hoisted to 186,000 metric tons monthly, when a major accident occurred in No. 2 shaft. It caused extensive damage to the shaft and milling had to be reduced to two-thirds of normal capacity. It was expected that the shaft would be operating again in January 1964 and that by March 1964 normal production of about 181,000 tons of ore monthly would be achieved.

Rose Deep announced that profitable operation no longer was possible.[14] Indications were that by June 1964 underground operations would cease. The mine produced 49,307 ounces of gold in 1962. From the start of operations to December 31, 1962, the mine produced more than 9.5 million ounces of gold.

It was reported that increased production and improved efficiencies resulted in a decrease in unit production costs at President Steyn, President Brand, and Welkom. However, at Free State Geduld and Western Holdings there were nominal increases in costs, despite the

[14] Mining Magazine. V. 109. No. 6. December 1963.

Digitized by Google

benefits of increased tonnages and efficiency.[15] These gold mines in the Orange Free State are controlled by Anglo American Corp. of South Africa, Ltd.

Iron and Steel.—Except in areas of special steels, South African iron and steel production has exceeded the needs of the country, and exports have been substantial. In recent years, however, rapid expansion of the South African economy has resulted in short supply of some types of steel.

The government controlled and operated South African Iron & Steel Industrial Corp. (ISCOR) continued to be the dominant company of the industry. ISCOR produced 82 percent of the ingot steel manufactured in South Africa in 1962. Other companies include African Metals Corp., Ltd. (AMCOR), and Union Steel Corp. (of South Africa), Ltd., (USCOR); ISCOR has a financial interest in both.

By November 1963, the steel shortage had become severe enough for ISCOR to announce restriction of domestic orders for steel to "the average of recent performance." The expression was defined as the level of orders during the past 1 or 2 years, meaning preboom levels. In December it was reported that every effort was being made to bring in a new plant and equipment as rapidly as possible, and to meet the rapidly rising demand, ISCOR was limiting exports to products in sufficient supply.[16]

ISCOR has in progress a plan begun in late 1961 for expanding steel-production capacity, designed to make South Africa virtually self sufficient in iron and steel by 1969. Annual steel ingot capacity of about 2,130,000 metric tons, was scheduled to be increased to 3,630,000 tons. In this connection the corporation in 1963 was trebling the capacity of its Sishen iron mine ore, to approximately 4.5 million tons. This goal was expected to be reached late in 1964.[17]

Early in 1963 Anglo American Corp. of South Africa, Ltd., announced that it was investigating the possibility of producing steel from titaniferous-vanadiferous magnetites of the Bushveld complex, by a process indicated to resemble the Strategic Udy process. Pilot plant tests had yielded encouraging results. Titanium reportedly can be eliminated, and vanadium can be recovered as a by-product. British experts were studying steelmaking aspects of the project.

AMCOR was expected to begin shipments of pig iron to Japan early in 1964, against its contract to deliver about 4.5 million metric tons of pig iron over a 10-year period.

USCOR proposed to spend R19 million in expansion projects over a 5-year period ending December 1967. Sales of mild and special purpose carbon steels in 1962 were nearly 16 percent higher than in 1961.[18]

Manganese.—South Africa has produced manganese ore and ferromanganese for many years. Ore reserves are very large, but no authoritative estimate is available. Battery-grade manganese dioxide and electrolytic manganese metal were also produced in 1963.

Manganese Ore.—Production in 1963 was about 40 percent greater than in 1958. Capacity is twice the 1963 output, the limiting factor being rail-transport capacity to distant consumers and ports of export. Exports and local sales in 1963 were, respectively, 902,446 and 452,491 metric tons. Fluctuations in these figures have been minor since 1960, when exports increased sharply and local sales moderately.

Exports generally go to 12 or more countries. In 1963 France and West Germany were the principal recipients with Belgium and the United States ranking third and fourth. Historically, however, the United States has stood first, in 1961 taking more than 200,000 metric tons, or about 27 percent, of South African total exports that year.

No breakdown by end use is available for local sales of manganese ore. Ferromanganese manufacturers accounted for major consumption of richer ores. South African uranium extraction plants were large consumers of low-grade ores. These plants continued to use the acid process for dissolving uranium, in which manganese ore is added to maintain required oxidizing conditions in the solution.

The Republic has two, main, widely separated manganese fields. The more important field, generally known as the Postmasburg field, was discovered in 1922. In this field deposits of manganese and also important iron-ore deposits occur at widely spaced intervals from about 56 kilometers south of Postmasburg, Northern Cape Province, north about 240 kilometers to Black Rock near the Bechuanaland border. The size, shape and attitude of the deposits and the situation with respect to overburden are such that except in one instance the deposits are mined open pit.

The manganese ore is unusually hard and does not disintegrate in storage, thus being excellent for exporting. The ore minerals are mostly manganite and braunite. The bulk of the ore is medium to low grade and high in iron but has low phosphorus and silica content. Typical analyses of three grades of ore appear below:

	Guaranteed minimum Mn, 48 percent	*Guaranteed minimum Mn, 44 percent*	*Guaranteed minimum Mn, 38 percent*
Manganese	49. 26	45. 96	40. 33
Iron	10. 82	13. 33	14. 91
Silica	2. 84	2. 41	2. 24
Barite	1. 28	1. 09	1. 61
Phosphorus	. 046	. 039	. 044
Alumina	4. 53	4. 98	8. 10

In recent years in what is known as the Kuruman part of the field, manganese ore has been found that is much lower in iron and richer in manganese than that for which the analyses are given. Some of these new ores have manganese to iron ratios of 7 to 1 and even 10 to 1. Manganese content reaches 55 percent, but in such ores iron content may also be high. These ores, generally blended to obtain a suitable ratio of manganese to iron, have been mostly consumed in South Africa in ferromanganese manufacture.

Few, if any, companies operating in the Postmasburg field reported production. The largest producer, however, has been Associated Manganese Mines of South Africa, Ltd., with South African Manganese Ltd., ranking second. The former company, also the largest exporter of manganese ore, produced iron ore from its Postmasburg properties,

Digitized by Google

and large tonnages of ferromanganese through a subsidiary, Ferroalloys, Ltd., at Cato Ridge, Natal Province. The annual report of Associated Manganese for 1962 indicated that ore tonnages sent by rail from its properties were about 523,000 metric tons of manganese ore and 406,000 tons of iron ore.

South African Manganese, Ltd., indirectly is owned or controlled by the government-controlled South African Iron & Steel Industrial Corp. (ISCOR), which accounted for about 80 percent of South African iron and steel production. South African Manganese, Ltd., holdings in the Postmasburg field are extensive, both for manganese ore and iron ore. In its Hotazel mine in the Kuruman part of the field the company, since 1961, has developed a large manganese ore body. Ore output planned for this mine is about 435,000 metric tons per year.

The other manganese area is not as sharply delimited as the Postmasburg field. It is in Transvaal Province, mainly in the Krugersdorp, Randfontein, Ventersdorp, and Marico Districts. Deposits are smaller and in general lower grade than in the Cape Province field. It is believed that by far the largest consumption of the Transvaal ore has been by plants producing uranium.

Durban has been the chief port for export of manganese ore, with smaller tonnages going through Lourenço Marques, Mozambique. The rail haul from the Postmasburg field to Durban is about 960 kilometers. Port Elizabeth is substantially closer, and the completion in 1963 of mechanical ore-handling facilities there has lowered both transportation and handling costs for export manganese.

Ferromanganese.—Since 1958 South Africa has established ferromanganese capacity large enough to permit substantial exports. Present annual capacity is estimated at about 180,000 metric tons. Data on production and domestic consumption are not available. Exports in 1961 reached a record high for the country; in 1962 exports fell by nearly 41 percent. Of total 1962 exports, 30 percent went to the United States and Canada. The sharp decline apparently reflected increasingly keen competition from United States and other manufacturers. The three grades of ferromanganese listed below were manufactured; prices shown were quoted f.o.b. Myerton, Transvaal, by the South African industry late in 1963:

Grade:	Price per metric ton
70–75 percent Mn	R87.00
75–85 percent Mn and 0.75 percent C	232.00
80–85 percent Mn and 2.0 percent C	173.25

The principal producers were Ferroalloys, Ltd., at Cato Ridge, Natal Province, and African Metals Corp., Ltd. (AMCOR), at Kookfontein, Transvaal Province. Both companies used electric furnaces. AMCOR, controlled by African Iron & Steel Industrial Corp., Ltd., is believed the largest manufacturer of ferroalloys in South Africa. Ferroalloys, Ltd., had two furnaces and was erecting two others in 1963 that were expected to be operating early in 1964.[19]

[19] The Associated Manganese Mines of South Africa, Ltd. 1962 Annual Report. 1963, p. 3.

Digitized by Google

Battery-grade Manganese.—Production of battery-grade manganese dioxide was begun in June 1962 by General Manganese Products (Pty.), Ltd., at Krugersdorp, Transvaal Province. A second plant for such production was scheduled to begin operating in 1963, at Gapani, Western Transvaal. The owner is Marble Lime & Associated Industries. A pilot plant the company built in 1962 to test the feasibility of the project appeared to have turned out a product meeting specifications of battery manufacturers. The output of these plants was not available; that of General Manganese was expected to be sufficient to result in exports of battery-grade manganese dioxide.

Electrolytic Manganese Metal.—In February 1960, Electrolytic Metal Corp. (Pty.), Ltd., after a year or more of test work, began commercial recovery of electrolytic manganese from uranium plant residues, obtained from West Rand Consolidated Mines, Ltd., a gold and uranium producer. This was the first and only such production in Africa. The plant has since been expanded. Output has not been disclosed.

Platinum.—Available information indicates that in 1963 South Africa ranked second after Canada in free world production of platinum group metals. Output is by Rustenburg Platinum Mines, Ltd., from two large underground mines in Transvaal Province, one at Rustenburg and the other on farm Zwartklip No. 405, about 76 kilometers north of Rustenburg. These are the only underground mines in existence from which platinum is the primary product, possibly exclusive of U.S.S.R. The content of platinum group metals is approximately as follows:

	Percent
Platinum	71.5
Palladium	24.9
Rhodium	2.3
Ruthenium	1.1
Iridium	.1
Osmium	.1
Total	100.0

Gold, copper, and nickel are also recovered; part of the copper and nickel are as refined metal.

The platinum group metals are produced in unrefined form and go to Johnson, Matthey & Co., Ltd., of London for refining and selling. In recent years there has been an overall improvement in grade of products shipped. The products in 1963 comprised: (1) Blanket table platinum concentrates called metallics; (2) platiniferous matte; and (3) an enriched platinum-bearing product resulting from local treatment of part of the matte, by Matte Smelters (Pty.), Ltd., jointly owned by Rustenburg & Johnson, Matthey & Co.

Rustenburg did not disclose production, estimated at around 300,000 ounces in 1963. However, net revenue from metal sales was R7.6 million, compared with R7.3 million in 1961–62. Near the close of the year demand for platinum increased markedly and sales for the year increased about 10 percent. The United States, United Kingdom, and Japan continued to be the leading customers. On November 7, 1963, the price for Rustenburg platinum was increased to £30.25

Digitized by Google

Sterling per ounce. The increase was made in view of sustained upward movement in the Russian price.

Operations at company mines encountered no technical difficulties, and there was no change in average grade of ore mined. Ample ore reserves are available for future mining requirements.[20]

Tin.—Tin was first found in South Africa in about 1905. The combined value of metallic tin and tin in concentrates produced through 1963 was more than R37 million. Most of the output came from Transvaal Province. Since 1939 the major part of output has been tin metal, smelted by Zaaplaats Tin Mining Co., Ltd., from richer domestic concentrates and from small quantities of concentrates imported from South-West Africa. Lower grade domestic concentrates are exported, mostly to the United Kingdom, and tin metal is imported. The average value of production, exports, and imports during 1955–59 inclusive is given as follows:[21]

	Value
Tin produced	R1,200,000
Concentrates exported	1,020,000
Tin imported	1,320,000

The financial year of Union Tin Mines (Pty.), Ltd., which ended June 30, 1963, was successful. Higher than average grade ore was found in the N3 lode on the 10 level. Company technical advisers felt that 88,000 long tons of ore and 28,500 tons of marginal material had been developed. Operations seemed reasonably assured for 4 years. In the year ended June 30, 1962, 32,493 long tons of ore were milled and 246.4 tons of tin in concentrates was produced.[22]

Uranium.—The source of South African uranium is the gold ore of the Witwatersrand sedimentary basin, from which uranium oxide is a byproduct. As of January 31, 1957, the South African Atomic Energy Board estimated that reserves of gold ore totaling 1,000 million metric tons contained 340,000 metric tons of uranium oxide. Average uranium oxide content of the estimated reserves thus is about 312 grams per ton. This figure compared with actual per ton recoveries of uranium oxide by producers in 1962, ranging from 173 grams per ton to 983 grams per ton.[23]

Output of byproduct uranium from the gold ores began in October 1952, when West Rand Consolidated Gold Mines became the first gold mine in the world to produce the metal. The industry was established by an agreement of November 1950 between an American-British purchasing agency called the Combined Development Agency and the South African Atomic Energy Board, created by the South African Government to deal with uranium matters.

The need of the United States and the United Kingdom for uranium was urgent. This need both required production to begin as soon as possible and influenced financing of the project. The agreement for producers included interest-bearing loans to cover cost of plant construction and, based on a cost-plus formula, the price to be paid per

Digitized by Google

pound of uranium delivered. The average price per pound was about R8.5, later falling to R8.0.

Twenty-four mines ultimately were included in the program, treating annually about 22 million metric tons of gold mill tailings and producing almost 5,700 tons of uranium oxide worth more than R104 million. Profit on such production was more than R54 million. Additional profit of nearly R3.2 million was earned annually by the gold mines from manufacture of sulfuric acid used in the recovery process.[24]

It soon became apparent that excess free world production was beginning, requiring reduction of procurement from South Africa. In 1958, when South African annual-production capacity was about 7, 250 metric tons, the ceiling for the country was set at 6,023 tons per year. Later, in 1961, a "stretchout" scheme for deliveries was established. The original contracts with individual producers would have expired between the end of 1963 and the end of 1966, when 25,719 tons of uranium oxide would have been delivered. The stretchout called for delivery of that tonnage by December 31, 1970. In addition, the scheme replaced cost-plus prices with fixed prices related to prices being paid at the end of 1960.[25] It also resulted in some high-cost producers selling their quotas to low-cost producers for a negotiated per ton royalty.

The Italian chief of uranium research visited South Africa in 1962 to investigate the possibility of buying uranium for the nine reactors in Italy. He said South African uranium was the cheapest in the world.[26]

Vanadium.—South Africa began to produce vanadium about 1957. Output rapidly increased and in 1962 the Republic ranked fifth among free world producers. Products marketed comprise fused vanadium oxide (99.90 percent V_2O_5) and small quantities of ammonium vanadate (minimum 75 percent V_2O_5), essentially all of which was exported in 1962, principally to European countries. The value of exports was R2,365,237 in 1962, when Transvaal Vanadium Co. (Pty.), Ltd., a subsidiary of Anglo American Corp., was the sole producer. In European markets vanadium from the Transvaal is highly competitive with that of U.S. producers.

Titaniferous, vanadiferous magnetite deposits at Kennedy's Vale, south of Steelport and elsewhere in Transvaal Province, were the source of output. Exploration in 1958 of such occurrences in the Transvaal suggested that they comprised the largest vanadium resource in the Western World.[27]

A visitor to the mine of Transvaal Vanadium Co. at Kennedy's Vale early in 1963 reported that the central ore body outcrops along the top of a hill and dips at about 70 degrees. At the surface it is about 182 meters long and 24 meters wide. It contains about 2 percent vanadium oxide and 17 percent titanium oxide, the rest being largely magnetite. Reserves are estimated to total at least 12 million tons, sufficient for 50 or 60 years at the present production rate. Mining costs are about R0.50 per ton; truck transport costs, about R0.47; and rail haul-

age to Witbank, where the extraction plant is located, about R2.00, for a total cost of about R3.00 per ton delivered at the Witbank plant.[28]

During the year Transvaal Vanadium converted its renewable lease on its property into a continuing lease, indicating optimism for the future of the undertaking.[29]

These Transvaal titaniferous-vanadiferous magnetites were being investigated in 1963 as possible raw material for steel manufacture with recovery of byproduct vanadium.

NONMETALS

Asbestos.—South Africa continued to be a leading world producer of asbestos. Output generally has ranked fourth by value among the minerals the Republic produces, exceeded only by gold, diamonds, and uranium. The country is in a unique position among asbestos producing countries in that it supplies the three principal varieties of fiber. Besides small quantities of tremolite, the following distinct varieties (ranked in order of value of the output in recent years) have been regularly produced: Crocidolite, amosite, and chrysotile. South Africa is the sole commercial source of amosite in the world. Reserves are large. With respect to crocidolite resources and production, Australia is the only serious competitor. Combined exports and local sales of the three varieties in 1962 were valued at R23,137,255, with the breakdown by variety as follows:

	Crocidolite		*Amosite*		*Chrysotile*	
	Quantity, metric tons	*Value* [1]	*Quantity, metric tons*	*Value* [1]	*Quantity, metric tons*	*Value* [1]
Exports	78,900	R12,384,008	63,193	R6,782,481	24,982	R2,912,188
Local sales	3,631	478,112	2,913	202,023	5,051	378,443
Total	82,531	12,862,120	66,106	6,984,504	30,033	3,290,631

[1] Export values are f.o.b. port of shipment; local sales value, f.o.b. at mine.

South Africa regularly furnishes asbestos to more than 40 countries, the largest importers being the United Kingdom and the United States. Particularly large exports of amosite asbestos to the United Kingdom can be attributed to the fact that a large United Kingdom asbestos fabricator controls the only producing amosite mine. With respect to crocidolite, about 90 percent of South African exports go to Europe.

Local use of asbestos has been principally in manufacture of asbestos cement, brake linings, and insulating materials. No substantial increase in local sales has occurred in recent years.

Amosite.—The mineral occurs in Transvaal Province at intervals in banded iron formation extending from Chunies Poort south of Pietersburg to the Steelpoort River north of Lydenburg. The Penge mine, indirectly owned by Cape Asbestos Co. (Pty.), Ltd., the only producer, had by far the largest reserves. Penge remained the largest asbestos mine in South Africa and the only large amosite mine in existence, a status attained in recent years as the result of extensive diamond drilling, shaft sinking, and underground development, which has shown the ore bodies to persist both laterally and in depth. In

[28] U.S. Consulate General. Johannesburg. Airgram A-331, Mar. 12, 1963.
[29] Mining Journal (London). Feb. 28, 1964.

Digitized by Google

recent years Penge has accounted for about 90 percent of world output of amosite.[30] In mid-1963 it was expected that ore output, then at the rate of about 72,500 metric tons per month, would be increased to 97,000 tons.[31] This would mean in terms of marketable amosite about 81,600 tons per year. Ore reserves appear sufficient for several decades at that rate of production.[32]

Crocidolite.—Crocidolite occurs both in the same belt as the amosite and in Cape Province in banded iron formation, extending about 400 kilometers from about 48 kilometers south of Prieska on the Orange River north through Griquatown and past Kuruman to the border of Bechuanaland. Two-thirds or more of total production usually comes from the Cape Province Belt. The largest producer there is Cape Asbestos Co., Ltd. A substantial contributor is Griqualand Exploration and Finance Co., Ltd., with six mines. At the start of 1963 most crocidolite operators had large stocks on hand.

Chrysotile.—Msauli Asbestos Mining & Exploration Co., Ltd., is the largest producer of chrysotile asbestos in the Republic. Its mine is in Transvaal Province on the Swaziland border. Production of milled fiber in 1962 totaled 15,260 metric tons. The ore reserve as of June 30, 1962, was reported to be about 2.9 million tons, the same as in 1961.

Diamonds.—Diamonds triggered mining activity in South Africa. Their discovery in 1870 at Kimberley and the subsequent profitable exploitation of the field both aroused worldwide interest in South Africa and provided much of the capital later poured into development of the Witwatersrand goldfields.

The South African industry is virtually monopolized by De Beers Consolidated Mines, Ltd. Either directly or through subsidiary companies, De Beers controls all the major privately owned diamond producers in South Africa; the government-owned workings in Namaqualand are the only major South African source not controlled by De Beers. In addition, through a subsidiary company, The Diamond Corp., Ltd., De Beers contracts periodically to purchase diamonds produced outside South Africa and South-West Africa. De Beers has an agreement whereby all sales of Russian gem diamonds to free world countries are made through De Beers.

The mining companies of the De Beers Group, the Diamond Corp., and the South African Government (for its diamond operations) belong to the Diamond Producers Association, formed in 1934 to regulate the industry. All sales of diamonds by members are put through the Association. For gem diamonds, quotas are assigned each producer. A further quota is allocated to the Diamond Corp. with respect to its purchases of diamonds outside South Africa. Quotas do not apply to sales of industrial diamonds.[33]

In recent years roughly 85 percent of South African production of natural diamond has come from large-scale underground mining of diamondiferous kimberlite pipes, and 15 percent has come from alluvial deposits. The principal pipes mined in 1963 were the Premier

near Pretoria; Wesselton, Bulfontein, and Dutoitspan in Kimberley; and Jagersfontein in the Orange Free State. Alluvial operations center in Namaqualand. For the whole industry it is estimated that of the order of 58 percent of output comprises industrial diamond and 42 percent gem diamond. South Africa also produces synthetic diamond.

Natural diamond production has increased steadily in recent years. Output in 1963 was 45 percent larger than in 1958. Sales in 1963 were valued at R36.6 million, compared with R15.5 million in 1958.

The De Beers Organization in South Africa sorts into parcels for sale the bulk of diamonds produced in all Africa. Sorting of gem diamond is done in Kimberley and of industrial diamond in Johannesburg. Exports of these parcels of raw diamond go principally to the United Kingdom, the United States, Ireland, and Continental Europe. Ultimately the United States is also a principal recipient of them from the United Kingdom and elsewhere. Cut and polished stones, of which South Africa is a significant manufacturer, in 1962 went chiefly to Belgium, Hong Kong, the United States, and the United Kingdom.

The total value of South African diamond exports in 1962 was R131.4 million, the breakdown of the total by source and kind being as follows:

South African origin:	*Millions of Rands*
Rough, uncut	R50.4
Cut and polished	22.8
Synthetic	1.1
Mixed origin, rough, uncut	57.1
Total	131.4

De Beers diamond sales on world markets were R231.9 million in 1963, an increase of R39.4 million over sales in 1962, a new record, and about 80 percent of all diamond sales. Sales of South African diamonds were 19 percent of the total value of De Beers sales in 1962. Early in 1963 De Beers increased the level of diamond prices by 5 percent, the first such general increase since about 1957.

It was expected that the old De Beers mine at Kimberley, closed since 1908, would be reopened in about September 1963 and reach full scale production in 1965.

De Beers announced in May 1963 that it had bought Finsch Diamond (Pty.), Ltd., for R4 million. Finsch has a kimberlite pipe near Postmasburg which De Beers had been exploring for nearly a year.

The West End diamond mine at Postmasburg will be reopened in 1963 at a cost of R200,000. This is a pipe from which largely gem diamonds reportedly were produced.

Early in 1963 De Beers entered into an agreement with S. V. Collins, of "diamonds-from-the-sea" fame whereby De Beers will lend R2 million for the right to market production of Marine Diamond Corp. and for first refusal on any stock in Marine which Mr. Collins wishes to sell.

Production of synthetic diamonds was maintained at planned levels during the year. A factory like that in South Africa is to be built at Shannon, Ireland, to serve the North American and European markets more efficiently.

Digitized by Google

In his statement of May 1964, accompanying the annual report of De Beers for 1963, Mr. Oppenheimer, De Beers' Chairman stated that on account of the Russian support for the boycotting of trade with South Africa, De Beers' contract to buy Russian diamonds was not renewed.

Phosphate.—For many years South African consumption of raw phosphates for superphosphate manufacture and direct use has increased virtually without interruption. Requirements have been met in part from domestic sources but mostly by imports, principally from Morocco. However, by yearend 1963, it was evident that the Republic would soon be self-sufficient in raw phosphates.

Four companies mine phosphates at present. Of these, State-controlled and operated Fosfaat-Ontginningskorporaise (Edms.), Beperk (Phosphate Development Corp. (Pty.), Ltd., or FOSKOR) is by far the most important. In 1962 FOSKAR contributed more than 50 percent of the 307,000 metric tons of crude phosphates the country produced.

FOSKOR mines the phosphate mineral, apatite, from the mineral complex at Phalaborwa, Transvaal Province, described earlier. Taking into account two distinct types of ore, ore reserves total about 100 million tons.[34]

FOSKOR completed construction of its new plant in April 1963. Annual capacity is about 317,000 metric tons of phosphate concentrate. The capacity of the new plant when added to that of the existing plant, about 166,000 tons annually, will be sufficient to eliminate immediate future needs for phosphate rock imports, which have been approximately 363,000 tons annually.

The report of the Viljoen committee of inquiry into the South African fertilizer industry was tabled in Parliament in July 1962. It foresees single superphosphate consumption of 1 million tons annually by 1965.[35] To meet the need 300,000 tons would be manufactured at two existing plants on the coast near Durban and Cape Town. The remainder would be manufactured by three inland plants of equal capacity: Fissons at Sasolburg, which has been expanded; Modderfontein, near Johannesburg, which was completed in March 1963; and a new plant at Phalaborwa, which would use sulfuric acid that will be available from copper smelting operations to be undertaken nearby (see copper).

Pyrite.—South Africa manufactures large quantities of sulfuric acid principally for use in uranium recovery plants and manufacture of fertilizers, explosives, and chemicals. Annual acid capacity is indicated to approach 900,000 metric tons. The bulk of the sulfur needed comes from domestic pyrite. While imports of elemental sulfur in 1962 were 118,000 tons, much of this was believed to have been used for purposes other than acid manufacture.

Production of pyrite in 1963 was 416,161 metric tons. The great bulk of the tonnage was byproduct pyrite recovered by certain gold mines. Several of these mines also have auxiliary sulfuric acid plants. For 1962, seven gold mines reported profits from pyrite and/or sulfuric acid, in amounts ranging from R107,909 to R714,667.

[34] The Government Printing Office, Pretoria. The Mineral Resources of South Africa. Fourth ed., 1959, p. 622.
[35] This will require roughly 500,000 tons of raw phosphate.

Digitized by Google

MINERAL FUELS

Coal.—Proved reserves of coal in South Africa total some 25 billion tons. There is in addition of the order of 50 billion tons of known coal which has not been thoroughly investigated. The proved and indicated reserves comprise more than 80 percent of the estimated coal reserve of Africa.

Coalfields.—South African coal is widely distributed geographically. Aside from certain inferior coal, fields occur in Orange Free State Province, Northern Natal Province, and northwards from Natal through Transvaal Province into Central Africa. In order of maturity of the coal, major South African fields are Northern Orange Free State (Vereeniging), Springs-Heidelberg, Ermelo-Breyten, Witbank-Middleburg, and Northern Natal.

In the first two fields are two to three seams with thicknesses in places as much as 60 feet. This is low-rank coal, used chiefly for space heating and by large electric power stations situated at the colliery.

In the Breyten field are three seams but only one is of sufficiently good quality to work, taking into account mining costs and transportation charges to distant markets.

In the Witbank field five major seams occur, but not more than two are usually worked. This is the most important field for quality of coal, reserves, and production. To conserve limited reserves of coking coal, some Witbank coal is used as a blend coal in coke production.

The Natal fields have the most mature coal. They provide the entire supply of coking coal, mostly furnished by two Natal collieries. Anthracite or semianthracite also comes from these fields, this coal resulting from the carbonization of bituminous coal by heat given off from sills of igneous rock which occur near the coal.

Mining.—South African coal is among the cheapest in the world because of relatively low cost labor and because the coal is thick and flat and occurs at shallow depths. Mining is by the room-and-pillar method. At Witbank inclined shafts are used, and the coal is usually brought to the surface by conveyor belt. For the whole industry, output per man-shift is about 3.2 metric tons for hand mining and as much as 10 tons for mechanized mining.

Organization and Facilities of the Industry.—In 1961, 53 collieries were operating. Six of these in the Orange Free State fields were producing annually more than 2 million tons each; one was supplying Sasol, the oil-from-coal plant; others were near large powerplants. In the Transvaal 7 collieries were each producing more than 1 million tons annually; 11 more than a half million tons.

Expansion of the industry was expected to continue in 1964 with the opening of two new anthracite mines in the Paulpietersburg area.[36]

Transvaal and Orange Free State producers belong to an association that distributes output of members, except coal supplied by a member to gold-mining-industry power stations under a special contract, and some coal supplied directly by members to the Electricity Supply Commission and the iron and steel industry. Natal producers have a similar but separate arrangement for bituminous coal and anthracite.

---

[36] Mining Journal (London). Mar. 20, 1964.

Digitized by Google

In part due to the efficiency of the Association 1961 f.o.b. prices per short ton for first grade coal ranged from R4.24 to R4.68, despite long rail hauls to market from most of the fields. At colliery, prices per short ton ranged from R1.22 to R2.00.

Rank of Coal.—South African bituminous coal (volatile content more than 14 percent) customarily is divided into the following three market grades: (1) High grade—6,900 calories per gram or higher. (2) medium grade—more than 6,470 calories per gram and less than 6,900 calories per gram, (3) low grade—from 4,850 calories per gram to 6,470 calories per gram. Anthracite sold, usually has a volatile content less than 11 percent and a calorific value greater than 7,170 calories per gram.

Few of the thick seams now mined are uniform enough to have an average calorific value higher than 6,900 calories per gram. Usually high-grade bottom coal deteriorates to inferior top coal. Such seams are worked selectively. Minimum thickness for economic mining is about 2.7 meters.

Consumption.—The breakdown of domestic consumption of coal is roughly as follows: [37]

Use:	*Percent*
Generation of electricity	39
Industry and domestic	21
Railways	18
Carbonization and gasification	15
Mining	6
Bunkers and exports	1
Total	100

Production.—Coal being the energy base of South Africa, the industry has expanded steadily with the economic growth of the country. Production in 1963 increased 1.25 million metric tons from that of 1962, establishing a new record. The 1963 output was nearly 60 percent larger than 12 years earlier. The value of sales was R65.9 million, compared with R65.1 million in 1962.

Foreign Trade.—The position for expanding coal exports to Europe and elsewhere in competition with U.S. producers is a difficult one. Most of the coal ranks lower than U.S. coal available for export, and the haul from coalfields to ports is somewhat lengthy, roughly 430 kilometers. In addition, the railroads at times have been unable to take all coal available. Exports in 1962 were more than 1.6 million metric tons, nearly 55 percent larger than in 1961.

Petroleum.—Annual consumption of all fuels is about 37 million metric tons of coal equivalent. Petroleum fuels comprise about 10 percent of the total, and gasoline accounts for about 50 percent of all petroleum fuels consumed. Consumption of petroleum products has been increasing at an average annual rate of 5 percent.[38] Substantial refining capacity exists, but the country still depends on imports for crude petroleum, none having been discovered to the present. The Sasoloil-from-coal operation somewhat alleviates the

[37] P. N. Lategan. The Coal Mining Industry of South Africa. Pres. to The Seventh Commonwealth Min. and Met. Cong., Johannesburg. 1961.
[38] South African Mining and Engineering Journal. Jan. 3, 1964, p. 6.

Digitized by Google

need. In 1960 domestic production of liquid petroleum fuels from imported crude was 8.2 million barrels. Sasol produced 560,000 barrels from coal; more than 85 percent was gasoline.

South African crude oil supplies come from Middle East territories and are shipped via Kuwait, Bahrein, and Abadan. The territories are also the chief source of refinery products imported, except that lubricating oils mostly come from countries of the Western Hemisphere. Imports of crude oil and of refinery products in 1962 were respectively, 12 million barrels, valued at R13.9 million, and 21.5 million barrels, valued at R62.6 million.

The government financed and operated South African Coal, Oil & Gas Corporation, Ltd., (Sasol) was incorporated in 1950. Its Fischer-Tropsch synthesis plant situated on a coalfield 80 kilometers south of Johannesburg is one of the largest such plants in the world, if not the largest. The extractable coal reserve available to the plant is about 300 million tons, sufficient for 50 years or more at any production rate the plant is likely to realize.

Late in 1963 a new US$45 million refinery owned equally by Shell and British Petroleum went on stream at Durban. According to a government publication, the plant will refine to 3 million tons of crude oil a year, saving South Africa an estimated US$10 million annually in foreign exchange. African sources estimate the capacity to be more than 60 percent of existing oil refining capacity, and 15 percent of that of the African continent.[39]

A 12-inch-diameter pipeline for refined products is to be laid from sea level at Durban 708 kilometers to Johannesburg at an elevation of 1,900 meters. The estimated cost and time for completion are R20 million and 3 years.

World Petroleum reported in March 1963 that a group of oil companies would begin large-scale exploration in South Africa. The group, which included French, German, British, and American companies, had obtained prospecting permits for 777,000 square kilometers and planned to spend about US$36.4 million.

It was reported that the Foreign Minister of South Africa urged South Africa to search for oil and to increase synthetic oil production to safeguard against possible oil boycott. He was reported to believe that new synthetic oil plants should be undertaken, because South African resources of low-grade coal and water are nearly inexhaustible.

The Mineral Industry of the Territory of South-West Africa

By Thomas C. Denton [1]

IN 1963 the mineral industry of the Territory of South-West Africa continued both to play the dominant role in the overall domestic economy and to contribute significantly to world mineral supply. The industry is the largest contributor to national income and export earnings and a large employer of labor. National income in 1962 was estimated at 181.52 million rands [2] of the Republic of South Africa and mineral sales were R52.13 million,[3] the indicated contribution of mineral industry to national income thus being nearly 29 percent. In 1962 the exports of the Territory were estimated at US$96.7 million, to which minerals contributed 54 percent. This compares with 24 percent and 22 percent, respectively, for fish products and agricultural production, the next most significant contributors. Labor employed by the industry in 1962 comprised 8,734 nonwhites and 2,003 whites.

South-West Africa in 1963 furnished 1 percent or more of free world production of beryl, cadmium, diamonds, germanium, lead, lithium minerals, vanadium, and zinc. For germanium, the Mandate is either the world's largest producer or second largest after the Republic of the Congo (Léopoldville). Other minerals produced in significant quantities included copper, silver, tin, and tungsten. Some 20 additional metals and minerals usually are produced.

The mineral industry of South-West Africa is largely in the hands of the four companies named below, the first two of which in recent years have contributed more than 90 percent of the mineral output by value:

1. The Consolidated Diamond Mines of South-West Africa, Ltd. (CDM). For many years CDM has accounted for virtually the entire diamond production of the Territory. At the end of 1963 De Beers Consolidated Mines, Ltd., owned 97.46 percent of the ordinary (common) shares of CDM.

2. The American-controlled company, Tsumeb Corp., Ltd. Tsumeb accounts for the great bulk of copper, lead, zinc, and silver produced and all of the cadmium and germanium.

3. The South-West Africa Co., Ltd. (SWAC), controlled by The Consolidated Gold Fields of South Africa, Ltd. SWAC is the sole

Digitized by Google

producer of vanadium and also produces some lead, zinc, tin, and tungsten.

4. Uis Tin Mining Co. (S.W.A.), Ltd. Uis, owned by the South African Iron & Steel Corp. (ISCOR), is the leading tin producer of the Territory.

The outstanding event in mining in 1963 concerns diamonds. By the end of the year it had been demonstrated that gem diamonds occur in gravels on the sea bottom off the South-West African coast, and results from mining operations conducted to the end of 1963 indicated that important quantities of sea diamonds can be recovered. The question of the extent and profitability of the deposits is extremely important to the Territory.

SOURCE MATERIAL

Major sources for this chapter were dispatches of the U.S. Consulate Generals at Johannesburg and Cape Town in the Republic of South Africa, publications of the South African and South-West African Government, trade journals, company reports, and personal observations.

PRODUCTION

The value of mineral and metal production in 1963 as measured by diamond sales, exports of other minerals, and nominal local mineral sales (mainly salt) was R62.2 million, up R10 million from 1962. Diamonds, of which about 95 percent were produced by CDM, contributed nearly 66 percent of the total, approximately the same as in 1962. The 19-percent increase in value mainly resulted from an increase of 41 percent in the volume of diamonds marketed. The volume of diamonds produced rose by 16 percent. Exports of Tsumeb products contributed about 30 percent of the total, and included 19,118 metric tons of blister copper valued at R8.1 million.

TRADE

Detailed breakdown of South-West Africa mineral and metal imports cannot be made because since 1955 the foreign trade statistics of the Territory have been incorporated with those of the Republic of South Africa. But mineral export statistics based on data supplied by the Inspector of Mines, Windhoek, are published separately by the Department of Mines of South Africa.

The major import by value presumably has continued to be petroleum fuels, coal, and coke. The Territory has no native sources of energy besides wood. Coal comes from South Africa, mostly by rail as far as 2,900 kilometers. Annual imports range around 275,000 metric tons. The bulk of petroleum products are imported by sea, mainly through Walvis Bay. Cargo landed there in 1961 and 1962 totaled, respectively, 282,503 tons and 256,517 tons; each year approximately 50 percent was identified as bulk oils. In addition, CDM imports petroleum fuels for its extensive operations, the tankers discharging directly into the company pipeline that extends out to sea from the property.

Diamond sales, equivalent to exports, in 1962 were valued at R34.2 million, about R700,000 less than in 1961. Destinations for the diamonds were not reported. However, the usual destination of most of the Territory production is London, the center for distribution of raw diamonds to the cutting industry.

All other mineral exports in 1962 were valued at R18.2 million, approximately R576,000 higher than in 1961. More than 88 percent of the total represented Tsumeb products, including concentrates of copper, lead and zinc with accessory silver, germanium and cadmium, germanium dioxide and blister copper. The germanium dioxide export was valued at R1.3 million. The blister copper was the first such export from South-West Africa. Lead vanadate concentrate and tin-tungsten concentrate produced by SWAC contributed, respectively, about R626,000 and R307,000. Tin concentrates from Uis were worth about R167,000. Exports of lithium minerals and salt were valued at R63,876 and R147,066, respectively.

By volume nearly 47 percent of the Tsumeb concentrates in 1962 went to the United States, 44 percent went to Belgium, and nearly 8 percent went to Japan. West Germany took 75 percent of lead vanadate exports, and the Netherlands and Belgium took the remainder. Germanium dioxide went to the United States and Belgium.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Beryl	93	117	United States 116; United Kingdom 1.
Bismuth concentrates kilograms		352	All to the Netherlands.
Cadmium, contained in concentrates	793	552	Belgium 256; United States 256; Japan 28.
Cesium, pollucite kilograms	179	508	All to the Netherlands.
Copper:			
Ore	4,610	1,463	Japan 1,311; Belgium 125; Sweden 30.
Contained in concentrates	23,966	22,290	United States 7,412; Japan 6,568; Belgium 6,206.
Blister		719	(1).
Germanium:			
Contained in blister copper kilograms		961	All to West Germany.
Contained in concentrates do	523	25,125	Belgium 19,519; United States 5,606.
Dioxide do	5,162	14,375	United States 8,001; Belgium 6,374.
Lead:			
Lead vanadium concentrates	8,430	7,716	West Germany 6,321; Netherlands 900; Belgium 495.
Contained in concentrates	58,306	70,224	United States 7,980 Belgium, 7,350.
Manganese ore	59,223	1,480	All to Norway.
Silver, contained in concentrates thousand troy ounces	1,833	1,253	United States 417; Belgium 401; Japan 302.
Tantalite/columbite kilograms	1,613	4,491	All to United States.
Tin concentrates	179	155	All to Republic of South Africa.
Tin/tungsten concentrates	366	539	Netherlands 377; West Germany 162.
Tungsten ore, scheelite		3	All to Republic of South Africa.
Zinc:			
Ores	2,062	2,950	All to United Kingdom.
Concentrates	2,402	15,909	United Kingdom 7,181; West Germany 5,240; Netherlands 1,820.
Contained in concentrates	21,012	19,850	United States 9,620; Belgium 9,319; Japan 753.
Nonmetals:			
Diamonds:			
Gem carats	787,949	800,498	(1).
Industrial do	119,597	142,690	(1).
Total do	907,546	943,188	(1).
Feldspar	90	477	West Germany 460; Netherlands 17.
Fluorspar		93	Republic of South Africa 91; Japan 1; United States 1.
Lithium minerals:			
Ambligonite	69	132	All to West Germany.
Lepidolite	836	1,339	Japan 1,137; West Germany 134; Netherlands 68.
Petalite	2,138	315	Netherlands 211; United Kingdom 104.
Lime-aragonite	(2)	4	Japan 3; China (not further identified) 1.
Phosphates, guano		240	All to Republic of South Africa.
Salt	40,931	39,478	Republic of South Africa 38,118; Rhodesia 1,129; Republic of the Congo (Léopoldville) 231.
Semiprecious stones:			
Amethyst quartz kilograms	298	4,336	United States 1,823; Republic of South Africa 1,361; West Germany 581.
Amazonite do		862	All to the Netherlands.
Rose quartz do	445		
Tourmaline do	5		
Cat's-eye do	4,300	1,361	All to West Germany.
Chalcedony do	1,179	2,150	All to the Netherlands.
Sillimanite-kyanite	2,758	1,975	Republic of South Africa 1,512; United States 463.

COMMODITY REVIEW

METALS

Copper, Lead, Vanadium, Zinc, and Associated Metals.—*Tsumeb Corp.*—The company operated two mines: Tsumeb, about 535 kilometers by rail northeast of the port, Walvis Bay; and Kombat, about 65 kilo-

Digitized by Google

meters south of Tsumeb. Production from Kombat began only in 1962, whereas Tsumeb has been operating for many years. Tsumeb mine has accounted for the entire output of germanium, zinc, and cadmium by the corporation, and the great bulk of lead, copper, and silver. Based on the gross value of metals contained in a ton of ore hoisted, Tsumeb mine is perhaps the righest large base metal mine operating today. From Kombat, moderate grade or containing copper, lead, and silver is produced.

TABLE 3.—Production of Tsumeb Corp., Ltd.[1]

(Metric tons unless otherwise specified)

	Quantity					Metal content, 1963			
	1959	1960	1961	1962	1963	Copper, percent	Lead, percent	Zinc, percent	Other reported

[1] Compiled from annual reports of Tsumeb Corp., Ltd. Years listed are fiscal years from July 1 to June 30.
[2] Began operations during last quarter of fiscal year 1961–62.
[3] Beside metals listed, a large quantity of germanium is produced both as dioxide and in concentrates.

Digitized by Google

Until recently the ultimate products of the corporation were concentrates which were shipped to overseas custom smelters and, beginning about 1961, some germanium dioxide. In November 1959 the Tsumeb Board of Directors authorized construction of a copper smelter at Tsumeb and in July 1960 a lead smelter and refinery, also at Tsumeb. The copper smelter was blown in on November 1, 1962, and the lead smelter by the end of 1963. Annual capacities of the new installations are 32,650 metric tons of blister copper and 81,650 tons of refined lead. About 180,000 kilograms of high-purity cadmium metal and 4,100 tons of sulfuric acid will also be produced. In addition the corporation expects to produce annually 1 million ounces of silver, 3,600 tons of arsenic trioxide, and germanium in forms more refined than in the past. Germanium production was expected to reach 15,000 kilograms annually. The ultimate effect of these projects is that exports of concentrates by Tsumeb will be virtually limited to some 10,900 to 13,600 tons of zinc concentrates annually.

The new smelters and ancillary facilities reportedly will have cost US$22.5 million.[4] About 78 percent of the material and 100 percent of the labor used were of South-West African and South African origin.[5]

The following details regarding corporation operations are for the year ended June 30, 1963. Net profit was R5.8 million, which compares with R8.5 million in the previous year. Metal sales were R22.8 million, compared with R24.6 million in 1961–1962. Provision of South-West Africa income tax was R14,930, which was small because heavy capital expenditures were incurred and under South-West African tax laws, capital expenditures are chargeable against taxable income in the year incurred.

In the Tsumeb mill overall recoveries in the various concentrates produced were 91.26 percent for copper, 95.45 percent for lead, and 45.18 percent for zinc in combined zinc concentrates. Milling rate was increased in February from 50,000 to 60,000 short tons per month.

In the Kombat mill overall recoveries were 96.46 percent for copper and 96.67 percent for lead. Metallurgical testing of mixed oxides and sulfides indicated that the slightly oxidized ores of the West ore body could be milled satisfactorily.

After minor modifications and mechanical adjustments, the copper smelter operated satisfactorily. It treated 38,910 metric tons of concentrates and other new metal-bearing material averaging 32.78 percent copper. Production of blister copper was 11,448 tons, averaging 98.78 percent copper and 1,245.6 grams of silver per ton.

In the arsenic plant, two roasters and other installations were completed, and experimental roasting of reverberatory furnace and germanium plant baghouse products was started. Progress was made in obtaining satisfactory arsenic elimination and production of calcined residues suitable for smelting and in production of high-grade arsenic trioxide for sale.

The sulfuric acid plant operated on imported sulfur, producing 3,035 metric tons of acid. The acid was used in the germanium plant. Construction of the gas cleaning plant continued. When it is completed,

[4] Mining Journal (London). Mar. 27, 1964, p. 239.
[5] Barclays Bank. Overseas Review. April 1964, p. 20.

Digitized by Google

sulfur dioxide gas will be delivered from the sinter machine to the acid plant.

The enlarged germanium roast, leach, precipitation plant operated at full capacity throughout the year. Construction of a plant for recovery of cadmium from lead smelter fumes was started.

From the surface 17,198 feet of diamond drilling was done further to explore the Tsumeb, Gross Otavi, Harasib, and Tsumeb West claims. At Gross Otavi two holes encountered encouraging copper-lead mineralization.

As of June 30, 1963 ore reserves were estimated as follows:

	Quantity, metric tons	Grade, percent			Total metal
		Copper	Lead	Zinc	
Positive ore:					
Tsumeb mine, above 30 level	6, 198, 233	4. 87	13. 20	3. 85	21. 92
Kombat mine	1, 292, 600	3. 22	1. 70	----	4. 90
Probable ore:					
Tsumeb mine, 30-34 level	2, 700, 000	4. 56	12. 49	3. 73	20. 78
Kombat mine	2, 010, 543	2. 39	3. 35	----	5. 74

Other Operations.—*The South-West Africa Co., Ltd. (SWAC).*—The company continued to operate the Berg Aukas lead-lead vanadate-zinc mine. In the year ended June 30, 1963, the expanded treatment plant operated throughout the year. As a result, the quantity of ore mined rose by 12,891 metric tons to 75,056 tons. Although production of lead vanadate concentrates was at a lower rate than in the previous year because of unfavorable market conditions, output of lead-zinc concentrates at 28,788 tons was 13,846 tons higher. Encouraging development results on the 510 level continued. The work together with underground diamond drilling increased total ore reserves to about 910,000 tons. Particularly encouraging was the increase of almost 50,000 tons in assured reserves of vanadate ore. At the end of the year it had become necessary to begin deepening the vertical shaft below the 500-foot level, then the deepest working in the mine.

Tin and Tungsten.—At the Brandenberg West mine of South-West Africa Co., Ltd., tonnages of tin-tungsten ore mined and milled during the year ended June 30, 1963, increased, with respect to those of the previous year, and output of tin-tungsten concentrates rose by about 26 percent to 717 metric tons. After providing for depreciation, the mine operated at a small loss during the year, due to low prices prevailing for wolframite and an average price for tin lower than in the preceding year.

Uis Tin Mining Co. (S.W.A.) Ltd., South-West Africa's other significant tin producer, was purchased by South African Iron & Steel Corp. (ISCOR) from private interests in 1960 to provide tin for ISCOR's growing tin plating operations. Low-grade tin deposits are in and around Uis near the Brandberg Mountains; ore reserves in 1962 were estimated at about 17.9 million long tons containing about 0.13 percent tin, according to the Inspector of Mines of South-West Africa. The ore is mined in quarries.

In 1963 Uis had in progress a R2-million-expansion scheme to increase production of tin-in-concentrates from 13 to 71 long tons a month, which would meet the needs of ISCOR indefinitely. Milling

Digitized by Google

capacity would be 58,000 tons of ore per month, including 13,400 tons of present capacity.

NONMETALS

Diamonds.—South-West African diamonds are sold in accordance with delivery agreements with the Diamond Producers Association, under control of the Administrator of South-West Africa, advised by the Diamond Board of the Territory.[6] The diamonds are principally gem diamond, the ratio of gem diamond to industrial diamond for the bulk of output being better than 9:1. This is by far the highest proportion of gems to industrials in any significant diamond field. The gem stones include stones considered to be the most beautiful in the world and in greatest demand.[7]

Until recently, production was almost entirely from gravels of ancient raised sea beaches that run parallel to the coast for miles and lie inland a few thousand feet from the present shoreline. Late in 1961, it was demonstrated that gravels containing principally gem diamond also occur on the sea bottom offshore. By the end of 1963 it had been proved that large quantities of these sea diamonds could be recovered. This unique development was due to the ingenuity and technical skill of S. V. Collins, a U.S. citizen.

In recent years diamond production of the Mandate has increased virtually without interruption. Output in 1963 was 1,194,629 carats, compared with 930,659 carats in 1959. In 1963 The Consolidated Diamond Mines of South-West Africa, Ltd. (CDM) contributed 1,138,050 carats, the small remainder presumably having come from sea operations. Sales in 1963 were as follows:

		Value rands	
	Carats	*Total*	*Average per carat*
Gem diamond	1,181,293	R39,585,949	R33.51
Industrial diamond	148,352	1,410,813	9.51

CDM.—Operations continued through 1963 in the various mining areas of the CDM diamond concession area along the coast north of the mouth of the Orange River. Steps were being taken to increase production. The output in 1963 was 131,141 carats more than in 1962. To achieve the 1963 figure, mining grade had to be increased from 0.35 carats to 0.37 carats per cubic meter. Additional field-screening plants will begin to operate during 1964, and grade will gradually return to normal. In millions of rands, financial results in 1963 were:

	Value million rands
Diamond account	R41.5
Interest, etc	6.8
	R48.3
Deduct mining and other expenses	8.6
Profit for the year	R39.7

The profit compares with R31.6 million in 1962.

Digitized by Google

At the end of 1962, gravel reserves were 74.7 million cubic meters estimated to contain 23.3 million carats of diamonds.

Diamonds From the Sea.—The following information regarding production of diamonds from the seabed off the coast of South-West Africa from the beginning of the operation to January 31, 1964, is based on a statement made by S. V. Collins.

In October 1961 the seagoing tug, *Emerson K*, was equipped as a prospecting vessel with machinery to process diamond-bearing gravels. On November 15, 1961, the first diamonds were discovered in Wolf Bay, south of Luderitz; on December 9, 1961, the *Emerson K* returned to Cape Town with 45 gem diamonds weighing 8.96 carats. By the end of March 1962 the *Emerson K* had sampled on a regional scale along the coastline from the mouth of the Olifants River (South Africa) to Luderitz, more than 600 kilometers, recovering more diamonds. The vessel continued to prospect with success.

A floating mining unit called Barge *77* was built, and active mining operations with it began in August 1962 in the Chameis area. On July 1, 1963, Barge *77* was driven ashore by abnormal gales. Barge *111* was built to replace it and began production 80 days after the loss of barge *77*. Barges *77* and *111* were not self-propelled. On January 8, 1964, a self-propelled unit, *Diamantkus*—purchased in the United States—began operations.

Production of these units from the beginning of the project through January 31, 1964, is given in detail below to the nearest carat:

Equipment and operating period:	Quantity Carats
Emerson K, prospecting:	
Oct. 16, 1961, to June 30, 1962	52
July 1, 1962, to June 30, 1963	90
July 1, 1963, to Jan. 31, 1964	21
Total	163
Barge *77*:	
June 16, 1962, to June 30, 1962	9
July 1, 1962, to June 30, 1963	51,917
Total	51,926
Barge *111*:	
Sept. 18, 1963, to Sept. 30, 1963	1,668
October 1963	7,006
November 1963	6,142
December 1963	5,537
January 1964	8,589
Total	28,942
Diamantkus: Jan. 8, 1964 to Jan. 31, 1964	7,987
Grand total	89,018

Gross proceeds from the sale of 73,563 carats was R1,681,509, representing an average value per carat of nearly R23.

The companies first to become interested in the sea diamonds were the holding company, Sea Diamond Corp., Ltd. (SDC), and the operating company, Marine Diamond Corp. (MDC). Late in 1963, at the christening of *Diamantkus*, the Administrator of South-West Africa announced that the ocean-bed diamond mining rights of MDC

Digitized by Google

had been extended seaward 3 miles, which increased the size of the concession about eight times. The venture already has cost about R6 million, and another R10 million may be spent on it in the near future.[8]

In October 1963 and earlier, De Beers and associated diamond companies concluded various agreements with S. V. Collins, MDC, and other sea-diamond companies. The agreements put De Beers in a position to acquire substantial interest in sea-diamond operations. Considerations, by De Beers for the position include a loan of R2 million and an agreement to survey and prospect 640 kilometers of coastline. In addition, the Diamond Corp. (De Beers) entered into an exclusive contract to purchase the production of MDC until the end of 1965. The survey and prospecting will be directed by a South African subsidiary of the American company, Ocean Science & Engineering Corp., which will use a specially equipped vessel, the *Rockeater*, expected to reach Cape Town in March 1964.

In his statement accompanying the report of De Beers for 1963, H. F. Oppenheimer, Chairman, said that production from MDC area was on "a considerable scale, and prospects look favorable." But it was still too early to assess long-term prospects.

MINERAL FUELS

Coal.—The Geological Survey of South Africa in drilling for water has found indications of coal at Kanorlei. Usable coal had been found earlier in that general area but at considerable depth.[9]

Late in 1963 the London & Rhodesian Mining & Land Co. offered to build a R40 million pipeline to carry coal to South-West Africa from the Wankie field in southern Rhodesia. A suggested route for the pipeline is from Wankie to Tsumeb and eventually to the coast. Southern Rhodesian coal would then be available for export both from the Atlantic coast and Indian Ocean ports. It was reported that such a pipeline would not pay unless utilized to deliver 2 to 3 million tons of coal per year. The present annual coal consumption of the Territory is approximately 300,000 tons.[10]

Petroleum.—The South African Government encouraged petroleum exploration in 1963, both in the country and in the Territory. In the latter, companies and individuals holding concessions included: Etosha Petroleum Co. (subsidiary of Texas Eastern Transmission); Diamond Dredging Co.; Trans-American Mining Corp., Suidwes-Africa Prospekteerders; Consolidated Diamond Mines; Artnell (Chicago); Veedol Minerals (Tidewater Oil-Getty interests).[11]

The Mineral Industry of the Republic of the Sudan

By Thomas G. Murdock [1]

THE SUDAN is Africa's largest country (374,000 square kilometers). Efforts have been made over a 50-year period to discover major ore deposits; however, the mining industry is practically nonexistent. In 1963, as in previous years, the activity consisted essentially of the small-scale exploitation of a few ancient gold mines and of production of marine salt and gypsum along the Red Sea coast near Port Sudan. Since 1949 cement has been manufactured in the country and since 1958 there has been small, intermittent production of several other minerals; however, the low grade of the deposits and high mining and transportation costs have made their exploitation unattractive. The most significant event of 1963 was the beginning of construction of a plant to refine imported crude petroleum. Copper deposits explored in recent years remained undeveloped, and petroleum exploration has been unsuccessful to date.

With the steady economic development in the Sudan since independence on January 1, 1956, the gross national product (GNP) had risen to Sd£436 million (US$1,260 million) [2] in 1962. Mineral production in that year was estimated to be worth only Sd£1,027,393, about 0.2 percent of the GNP.

GOVERNMENT POLICIES AND PROGRAMS

No significant mining or petroleum legislation was enacted during 1963, and the policy expressed in the Approved Enterprises Act No. 8 of 1956, which encourages private enterprise, has been continued. In the 1963 organization of the petroleum-refining company, the Government has an option to buy 50 percent of the shares. The general program of the 10-year plan was continued with satisfactory progress during the year and improvements in transportation, which hold a high priority in the plan, benefited the mining industry. Work continued at a satisfactory rate on the Roseires Dam in the eastern Sudan and provided a local market for cement, well above domestic production. This facility is scheduled for completion in 1967, and industrial development in the area is expected to create a growing market for

[1] Mining engineer, Division of International Activities.
[2] The monetary unit is the Sudanese pound (Sd£). Sd£1 = US$2.89, or US$1 = Sd£0.3460, is the exchange used in this chapter.

Digitized by Google

mineral raw materials. The Sudan Geological Survey Department continued its program of mineral resource investigation, particularly in the Qala en Nahal area and in the vicinity of the Roseires Dam.

SOURCE MATERIAL

Data on mineral production and activity are meager; reported production figures are usually official estimates, supplied to the U.S. Embassy by the Geological Survey Department. Data on trade are complete and reliable. Background information used came mainly from reports of a U.S. consulting firm prepared for the Agency for International Development (AID) and supplemented by published reports of the Sudan Geological Survey Department.

PRODUCTION

Except for chromite production, reported for the first time, there were no significant changes in production in 1963. Small quantities of clay, sand and gravel, building stone, and quartz were produced and utilized locally, however, no statistics on these were systematically collected.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:

[1] Part of this output may have been for previous years.
[2] Estimate.
[3] Exclusive of imported clinker ground locally as follows: 1959, 27,500 tons; 1960, 32,485 tons; 1961, 22,609 tons; 1962 and 1963, none.

TRADE

In 1962 the Sudan imported mineral and metal commodities valued at Sd£12.6 million (Sd£8.9 million in 1961). These comprised 14 percent of all imports (11 percent in 1961). By major categories the 1962 imports were fuels, Sd£6.1 million; metals, Sd£5.3 million; and nonmetals, Sd£1.2 million. These came from 45 countries; however, an aggregate of 57 percent came from Iran (31 percent), the United Kingdom (15 percent), and Belgium (11 percent). The European Economic Community as a whole supplied 27 percent and the Sino-Soviet bloc, 10 percent. Mineral imports from the United States amounted to only Sd£154,022 (1.2 percent of those from all sources) and consisted mainly of lubricating oils and rolled steel products.

Digitized by Google

These commodities comprised only 3 percent of all imports from the United States.

Exports of locally produced minerals, mostly to neighboring countries, were valued at only Sd£21,220 (Sd£37,870 in 1961), an insignificant part of the country's total exports, valued at Sd£75 million in 1962. Exports of nonindigenous mineral, metal, and fuel commodities were valued at Sd£572,512, including some fabricated metals which are not identified separately. Of this total, Sd£470,059 was for aviation bunkers. The foregoing commodities comprised 12 percent of all reexports.

TABLE 2.—Exports of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Iron ore	-------	2,000	All to Yugoslavia.
Ferrous scrap	4,900	-------	
Gold ---- troy ounces	113	419	All to United Kingdom.
Nonmetals:			
Cement	129	-------	
Lime	20	-------	
Salt	938	525	Ethiopia 199; Chad 177; Congo 133.

[1] Reexports of unstated quantities valued at Sd£776,245 in 1961 and Sd£572,512 in 1962 are reported. Bunker aviation fuels are included in totals, and values of these were 78 percent of total in 1961 and 82 percent in 1962.

COMMODITY REVIEW

METALS

Chromite.—The Mining & Trading Co., Khartoum, began exploitation of chromite deposits in the Ingessana Hills region near Bau, about 80 kilometers southwest of Roseires, within a concession granted in 1961. A few hundred tons of ore was shipped to France, about 8,000 tons was reportedly stockpiled in Port Sudan, and an additional 10,000 tons was stockpiled at the mine. The ore is trucked to Roseires, from which it is moved by rail to Port Sudan. Reportedly the company has had difficulty in selling the ore because of competition from other producing countries. According to a Sudanese official publication,[3] in spite of the limited number of exploitable deposits, the outlook is encouraging for a substantial production from the area. No data on average grade of ore produced are available; however, the chromite recorded in the Ingessana Hills contains up to 57.45 percent Cr_2O_3. The 1963 production came entirely from surface exposures, but prospects for continuity at depth were considered promising. Estimates were that 50,000 to 60,000 tons per year could be produced if markets open up.

Copper.—During 1963 African Mining Co., of New York, a U.S. registered firm controlled by an Italian financier, continued efforts to obtain financing to open up the Sudan's only known copper deposit, the Hofrat en Nahas in Southern Darfur Province, 320 kilometers from El Da'en, the nearest point on the existing railway. African Mining has held a concession for the deposit since 1962 following exploration

[3] Kabesh, M. L. The Geology and Economic Minerals and Rocks of the Ingessana Hills. Sudan Geol. Surv. Dept. Bull. 11, September 1961, 61 pp.

Digitized by Google

of the area by the Sudan Geological Survey Department and subsequent calling for international tenders. This exploration proved about 10 million tons of ore containing 2.78 percent copper. Old dump material contained 0.3 ounce of gold per ton, gold content of the copper ore was not determined. The remoteness of the area has discouraged development; reportedly a leading U.S. mining organization was interested in participating in the venture but would have to wait several years. More recent negotiations were with West Germans interests. In August a Sudanese Government official announced that production might be expected by 1965.

Gold.—In 1963 the Sudan's gold production came mainly from the Doishot mine in Northern Province and the Bir Kaneib and Gebeit in Kassalla. The latter, approximately 240 kilometers from Port Sudan and probably one of the oldest active gold mines in the world, was exploited by local inhabitants and produced 3 to 5 tons of ore per day from old workings in pillars above the 20-meter level. The ore was treated in a small stamp mill and the amalgam was retorted on the property; recovery averaged about 1 ounce per day of very fine gold. Additional gold associated with pyrite in the vein was not recovered in the absence of cyanidization facilities.

High production costs, even with the primitive mining methods used, and the exhaustion of easily accessible and high-grade ore in the few mines being worked are the causes of output reductions in recent years. The major market for Sudanese gold is the jewelry trade in Omdurman, across the Nile from Khartoum, where premium prices obtained, up to $55 per ounce and averaging $50.18 in 1962 constituted a virtual subsidy of operations.

Iron Ore.—Preliminary results of the exploration of iron ore deposits in the Sufaya region, 78 kilometers inland from Marsa Delwein on the Red Sea, became available in 1963. The exploration was carried out by the Yugoslav firm ELECTROSOND, of Zagreb. Within the areas explored, only the Ankura and Aderauib deposits have possible importance and the reserves of these are insignificant by world standards, totaling only about 11 million tons for all categories and having an average tenor of 47 percent iron. The low grade and volume and the distance to tidewater discourage development. The 20,000 tons produced in 1962 contained 60 percent iron, and trial shipments were made to JUGOMETAL in Yugoslavia.

No activity was reported for 1963 at the Fodikwan deposits of Central Desert Mining Co. of Port Sudan, 19 kilometers from the harbor of Marob. The limited reserve and low grade, revealed by the exploration that resulted in the small production of 1960, made development unattractive. Although a new railway extension from El Obeid to Wau passes close to El Fula, 110 kilometers south of En Nahud in Kordofan Province in western Sudan, where exploration revealed a reserve of 35 million tons, 1963 saw no renewal of the interest in the deposits.

Manganese Ore.—During 1963 Sudanese manganese producers were endeavoring to market accumulated stocks at their mines, and some exploration and a limited production may have been effected early in the year. The country's major deposits are in Kassalla Province, and the most recent recorded activity was at the Gebeit mine of National

Digitized by Google

Mining Co. and the Al Amar mine of Sayed Abdel Monim Samkart, situated, respectively, 85 kilometers north of the railroad town of Gebeit and 280 kilometers north of Port Sudan. While ore from these mines reportedly contains over 50 percent manganese, high costs of production and transportation to Port Sudan have discouraged exploitation.

Steel.—In March Compagnie Continentale des Produits, of Paris, won an international tender for supplying 25,000 tons of new rails to replace the lighter ones on the Khartoum-Atbara-Port Sudan line of the country's railroad system at the rate of 200 kilometers per year. The steel cost £33 (sterling) per metric ton, f.o.b. French ports.

NONMETALS

Asbestos.—In 1963 the Sudan Geological Survey Department continued its extensive exploration of deposits of chrysotile asbestos in the vicinity of Qala En Nahl in southeast Kassala Province, about 800 kilometers by rail from Port Sudan. The deposits could be mined by open-pit methods. Although official reserve figures have not been announced, there appears to be several hundred thousand tons of asbestos ore in the area which would yield a fiber recovery of at least 5 percent. A substantial portion of the fiber is of the short variety, but much spinning grade is obtainable. Several foreign asbestos consumers have shown interest in the deposits.

Cement.—During 1963 the extension (from 61,000 to 152,400 tons) of the Atbara plant of Sudan Portland Cement Co. was completed. The Nile Cement Co. continued construction of the country's second plant at Kosti, a locality better situated with respect to construction projects underway and proposed. The Kosti plant was expected to cost Sd£2.15 million, and capital for the venture was raised in part by public subscription.

MINERAL FUELS

Petroleum.—Following the November 1962 formation of Shell and BP (Sudan), Ltd., a joint venture in which the Royal Dutch Shell group and British Petroleum Co. are participating equally, the construction of a 1-million-ton-per-year refinery at Port Sudan was assured. In early 1963 the erection contract was awarded to the Dutch firm of Werkspoor, N.V., and actual construction began in August. Scheduled for completion in September 1965, this facility will refine imported crude and process domestic crude (should it be found, of suitable quality, in the Sudan), producing gasoline, jet aviation fuel, distillate, and residual fuel oil. Selected Middle East crude oil will be imported using large tankers. To provide qualified Sudanese personnel for the refinery, a training center was established at Port Sudan in January; other potential employees were sent abroad for training in operating refineries.

AGIP Mineraria (SUDAN), Ltd., continued its exploration program, which has been carried out since 1961, in its permits along the Red Sea coast and offshore, without success. Durwara 2 well, 2,949 meters deep, was completed during the year, and additional drilling

Digitized by Google

followed, probably at the Tokara 1 well. In October AGIP renewed its prospecting rights for 2 years at a reported price of Sd£20,000. Equipment in the Port Sudan area was dismantled and shipped out of the country but another type was to be brought in if further drilling was done.

In May, the Shell organization was awarded a contract to supply all petroleum requirements of the Sudanese Government for 3 years beginning July 1. The contract was valued at Sd£5 million. This company has always won this contract, probably because it is the only marketing organization with storage facilities in the southern provinces.

The Mineral Industry of Togo

By Thomas G. Murdock [1]

THE Republic of Togo, a former United Nations Trust Territory under French administration until it became independent on April 27, 1960, only entered the ranks of recorded mineral producers in 1961, with its first output of phosphate rock. Subsequent growth in production of this mineral gave Togo fifth place among African producers in 1963, replacing Algeria, with 1.1 percent of world total. Considering the high quality of the Togolese rock, this contribution was still more significant. With a population of 1.6 million, an area of only about 57,000 square kilometers, its limited industrialization, and essentially dependent upon agriculture, Togo continued to have only limited need for metal and mineral imports. However, in 1963 the value of these was 26 percent above that of 1962 and still higher than the value of phosphate rock exports; the latter became an important earner of foreign exchange and was exceeded only by the value of cocoa exports.

In 1962 the gross national product (GNP) was CFAF26,215 million (US$107 million),[2] and phosphate rock production was valued at CFAF506 million, 1.9 percent of the GNP. With the greatly expanded phosphate rock production in 1963, the value of output increased to CFAF1,144 million with a consequent rise in the share of the GNP contributed by mining.

Employment in phosphate mining and beneficiation consisted of about 60 supervisors and administrative personnel and 650 workmen of all categories, a small part of the total labor force, the size of which is not available.

At yearend U.S. investment included the phosphate industry and oil exploration. The U.S. participation in the phosphate project was believed to have been an important factor in the expansion of exports markets.

GOVERNMENT POLICIES AND PROGRAM

No new mining or petroleum legislation was reported. A coup d'etat in January reportedly delayed the activities of the company engaged in petroleum exploration, but the new government formed in May subsequently approved all contracts entered into by the previous regime.

Togo continued to favor development on a free-enterprise basis,

[1] Mining engineer, Division of International Activities.

[2] African Financial Community (CFA) francs are use in Togo. The exchange rate is US$1=CFAF245 (CFAF1=US$0.0040816).

Digitized by Google

welcoming foreign private capital and offering special tax incentives for approved investments. The specific terms of these incentives depend on the nature of the investment and are worked out on an individual basis. An investment guarantee agreement with the United States was effected prior to 1963.

A mineral exploration program began in February, with the aid of the United Nations Special Fund. This project was to last 2 to 3 years and hopes were that it might disclose deposits of economic importance, but at yearend no significant finds have been reported.[3]

SOURCE MATERIAL

Data on production, trade, and 1963 developments are from dispatches of the U.S. Embassy in Lomé. Background information and the description of the phosphate development came mainly from an article in the French press.[4]

PRODUCTION

Phosphate rock production began in 1961 with 117,897 metric tons of marketable product, increasing to 193,000 tons in 1962 and 587,500 tons in 1963; the 1963 increase resulted from the successful introduction of the high-quality rock into the export market, an achievement which was not possible immediately upon the earlier completion of productive facilities. Data on production of building materials are not available; indications are that except for cement and lime, Togo was self-sufficient. Indications of some reduction in production are reflected in the decline in permits for the construction of housing in Lomé, from 32,700 square meters in 1962 to 30,000 square meters in 1963.

TRADE

Data on trade in metals and minerals are not available in detail for any year since 1960. Prior to September 1961 exports of these commodities were limited to small quantities of scrap metals and imported petroleum refinery products. Subsequently, exports have been expanded significantly with the development of Togo's phosphate rock deposits. In 1962 exports of phosphate rock amounted to 184,723 metric tons valued at CFAF489 million (12 percent of all exports on basis of value), increasing in 1963 to 441,434 tons[5] valued at CFAF1,068 million (24 percent). Italy was the leading consignee for 1963 exports, with 109,164 tons, followed by Brazil (100,799 tons), France (59,586 tons), Japan (58,677 tons), Belgium (42,390 tons), and the United States (39,792 tons).

Imports of principal metals and minerals in 1963 had a total value of CFAF1,144 million, 16 percent of all imports (CFAF906 million and 14 percent in 1962). These consisted of iron and steel (excluding

manufactures), CFAF442 million; cement and salt, CFAF281 million; and refined petroleum products, CFAF421 million.

Italy, as the leading 1963 phosphate rock customer, received about 23 percent of the mineral exports on the basis of value, followed by Brazil (21 percent). The European Economic Community as a whole took 51 percent. Phosphate rock exports to the United States were 8 percent of the Mines Service total and on the basis of value were 27 percent of all of Togo's exports to that country.

Data on 1963 value of metals and minerals supplied by individual countries are not available. Their individual shares were reflected in the values of all imports which showed France supplied 30 percent; the European Economic Community as a whole accounted for 48 percent and the United States, 4 percent. Imports of refined petroleum products from the latter were valued at CFAF3.5 million, 1.1 percent of all imports from that source.

COMMODITY REVIEW

During the year United Nations geologists investigated a manganese deposit north of Dapango; indications were that an economic exploitation was unlikely. The limited bauxite reserves in the Mont Agou deposit, the marginal grade and high production costs of the Ahito chromite, and the remoteness to transportation for the Bangéli iron ore deposits continued to prevent any steps toward development of Togo's better known resources of metals.

Phosphate Rock.—Phosphate production, all by Compagnie Tongolaise des Mines du Bénin (CTMB) from its mine near Hahotoe about 22 kilometers from the sea, reached its highest level since mining began in 1961. The record output followed the 1962 acquisition of about 40 percent of the CTMB stock by the American firm of W. R. Grace & Co. which provided additional capital to finance production expansion plans and new customers through Grace's marketing contacts. Sales had been developing slowly in previous years, the result of introducing a new high-quality product into the competitive world markets. CTMB was founded in 1957 as a partnership of the French

Digitized by Google

Société Minière du Bénin, which had effected an extensive exploration of the area, and the Togolese Government which took 5 percent of the stock but reserved the right to purchase up to 20 percent. Prior to Grace's participation CTMB capital was reported at CFAF1,180 million.

The phosphate deposit opened up is of Eocene age. It has a thickness of 2 to 5 meters and is overlain by 6 to 25 meters of sand and clay; average overburden to phosphate rock ratio is 6 to 1. The reserve of crude rock is estimated to exceed 100 million metric tons, capable of giving marketable concentrates on the order of 50 million tons. The crude rock contains, in addition to moisture content, 25 to 40 percent of clay. Stripping with power shovels feeding conveyor belts began in late 1959, and in May 1961 a bucket-wheel excavator handling 1,200 cubic meters per hour entered service; by the end of 1961 total overburden removed was 1.5 million tons. A bucket-type excavator of a 250- to 300-ton-per-hour capacity has been used for mining, discharging the rock onto conveyor belts for loading into 25-ton cars. The latter moved in trains of 24, hauled by diesel locomotives, over the company's meter-gage railway to the beneficiation plant at Kpéme at the edge of the sea and 22 kilometers distant. A scarcity of water at the mine led to the installation at Kpéme; salt water at the rate of 2,000 cubic meters per hour is used in beneficiation, followed by a rinsing with fresh water obtained from beneath nearby sand dunes. The crude ore has been treated in the Kpéme plant which included two parallel circuits for the successive screening, treatment by hydrocyclones, dewatering by centrifuging and rotary kiln drying and subsequent rescreening and magnetic separation. Plant capacity was 200 metric tons per hour; the marketable product obtained in 1963 had an average P_2O_5 content of 37 percent. The "first quality" material which comprised 96 percent of the 1963 exports contained 36.6 to 37.6 percent P_2O_5 and the remaining 4 percent was "second quality" with 34.4 percent and was exported to the Republic of South Africa. The marketable concentrate moved by conveyor belt to the 60,000-ton storage shed for subsequent embarkation from the 1,200-meter wharf equipped with loading equipment of an hourly capacity of 2,000 tons and permitting vessels to moor in 13 meters of water. The total cost of the exploration, mine development, plant, and infrastructure was reported at CFAF6,370 million. Mine and plant equipment reportedly were capable of producing 750,000 metric tons of marketable product annually; expectations were that exports would reach about 600,000 tons in 1964 and 1,000,000 tons after an expansion of capacity.

Petroleum.—While little data are available regarding progress in the search for petroleum in Togo, indications are that the small U.S. firm, the Togo-American Oil Co., continued active. This company held a general exploration permit over 6 areas, covering a total of 4,145 square kilometers (2,895 in the Bas-Togo sedimentary zone and 1,250 in the bordering continental plateau). This was granted in 1961 and under the terms of the agreement with the Togolese Government the company was committed to spend at least CFAF1,500 million during the first 3-year period of validity of the permit. It was reported in 1963 [6] that the firm had done 3 months of geological and geophysical correlation work and subsurface analysis of water wells. Expectations

[6] World Oil. V. 157, No. 3, Aug. 15, 1963, p. 161.

Digitized by Google

were that the first wildcat well would be begun in the year. Azienda Generale Italiana Petroli (AGIP), the Italian-owned petroleum firm, began the construction of a petroleum storage depot, scheduled for completion in the first half of 1964. The depot is near the phosphate wharf at Kpéme, and a pipeline from the wharf to the depot will enable tankers to transfer fuel directly to the depot. Petroleum products were formerly shipped overland from Dahomey and Nigeria. The new depot will permit utilization of products from the AGIP refinery in Ghana, which could not be trucked in following the closure of the Togo-Ghana border, and will give AGIP a definite price advantage in the sale of its products on the Togolese border.

The Mineral Industry of Tunisia

By Thomas G. Murdock [1]

EXCEPT for establishing a record high for phosphate rock production, the mining industry of Tunisia showed little growth in 1963. The country is important to the world's mineral economy only for its production of phosphate rock; in 1963 it was the world's fourth largest producer, with 5 percent of the world total. Only small quantities of iron ore, lead, and zinc have been produced, and output of these has declined sharply over the past decade. An important development of 1963 was the completion of the petroleum refinery near Bizerte to treat imported crude oil.

The 1963 mineral production was valued at D15.5 million (US$36.89 million); [2] of this, phosphate rock comprised D8 million. The 1963 gross national product (GNP) was D346.6 million; thus, the extractive industry contributed 4.5 percent of the GNP.

At the end of November, the labor force engaged at metal and phosphate mines totaled 8,098 employees; the total including lead smelters and phosphate-processing plants was 8,774 (9,581 on January 1); this was 0.6 percent of the entire labor force, which is estimated at one-third of the population.

GOVERNMENT POLICIES AND PROGRAMS

No significant mining legislation was reported in 1963, and indications are that by yearend the program of nationalization of the mines was complete. Management was turned over to the Office National des Mines (ONM) attached to the Secretariat for the Plan and Finances, by Decree-Law 62–9 in early 1962, as part of the Government's control of commerce and industry.

Under the Government's current 10-year plan, the output of the mining industry is scheduled to be increased 43 percent by investments expected to total D147 million during 1962–71. Progress was slow in 1963, and only phosphate rock has shown expanded production. ONM is charged with exploration by the organic legislation, and was scheduled to carry out an extensive program of geological investigation; the only announced result to date has been the discovery of deposits of high-quality marble which might enable Tunisia to become a net exporter. Petroleum exploration was continued at about the same intensity as in preceding years.

During the year, several events indirectly affecting the mineral industry were reported. In April newspapers indicated that a new code

[2] The Tunisian monetary unit is the dinar (D). Exchange used in this section is D1=US$2.38 (US$1=D0.42).

Digitized by Google

for private investments was in an advanced stage of study; however, no details as to contents and final decision have been announced. In May a U.S. long-term loan of $15 million was made to Tunisia for financing competitive commodity imports from the United States; this was part of the $180 million 3-year U.S. aid commitment announced the preceding October. On July 15, several important amendments were made to the Social Security Law of 1960, providing further fringe benefits to workers.

SOURCE MATERIAL

Information on activity during 1963 is comparatively limited; it has been gleaned from dispatches of the U.S. Embassy in Tunis and supplemented by the partial coverage of the technical press. The statistical data came mainly from official annual and interim publications of the Tunisian Government.

PRODUCTION

Except for phosphate rock and a few minor commodities, production of metals and minerals has declined, with minor fluctuations, since 1959. Phosphate rock production dropped between 1959 and 1961, and that of 1963 was only 8 percent above that of 1959; world phosphate rock production rose 15 percent between 1959 and 1962.

TRADE

In 1962 the total value of metal and mineral exports was D14.1 million (D15.9 million in 1961) and comprised 29 percent of all exports; they consisted mainly of phosphate rock (D6.9 million), iron ore (D2.4 million), and lead (D1.0 million). Imports were valued at D13.8 million, 15 percent of all imports, compared with D13.9 million and

Digitized by Google

16 percent in 1961. The 1962 import values were metals D5.5 million; nonmetals D1.1 million; and mineral fuels D7.2 million.

France continued to be Tunisia's principal partner in metal and mineral trade in 1962, receiving 31 percent of the exports and supplying 74 percent of the imports. Italy ranked second with 20 percent of the exports and 15 percent of the imports. Exports to the United States were limited to 5 tons of magnesium scrap valued at D902; imports from this destination, for the most part rolled-steel products, comprised only 0.5 percent of the 1962 imports.

Based on trade in the most important items through November, the 1963 exports rose to about D14.4 million and imports to about D15.4 million.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:			
Aluminum:			
Crude	226	214	Italy 184; Belgium-Luxembourg 30.
Scrap	10	100	All to Italy.
Copper:

COMMODITY REVIEW

METALS

Iron Ore.[3]—The Djerissa mine of Société du Djebel Djerissa, 200 kilometers southwest of Tunis, continued to provide practically all of Tunisian iron ore production. Although the country's output in 1963 was 11 percent above that of 1962, it was still 18 percent below the 1960 high. The 1963 exports from Djerissa were 783,000 metric tons (667,000 tons in 1962). The Djerissa ore, with an iron content of 54 percent in 1962, continued to face severe competition from higher grade ores of other producing countries. In 1963 mining at Djerissa was by both opencut and underground methods, and extensive advance stripping of overburden was done in an area where mining is due to commence in 1965. Systematic exploration was continued in 1963, to add to the known reserve, reportedly sufficient for 15 to 20 years. Plans were formulated for deepening the basin at the port of La Goulette before the end of 1965, to enable loading of ore carriers of 10-meter draft.

Iron and Steel.—In 1963, Société El Fouladh, Tunisia's iron and steel enterprise, placed contracts for the proposed complex to be built on the south shore of the Bay of Bizerte. The blast furnace and sintering plants are to be supplied by the British firm of Ashmore, Benson, Pease & Co., Ltd.; the Swedish firm of Mogardshammors Mek is to furnish the rolling mill; and a French company, Société Anonyme des Entreprises Leon Ballot, is to execute the civil engineering work. Other Swedish and French companies are to provide other equipment and services. Initial annual capacity of the installation was an-

[3] Djerissa of Tunisia. Metal Bulletin (London). No. 4844, Nov. 5, 1963, pp. i–iv.

Digitized by Google

nounced at 70,000 metric tons of rolled products; expectations were that this would be doubled by 1971.

To provide wide participation in the investment, shares of D5 were offered for sale to the general public. Plans were to raise D0.5 million by popular subscription, with the Government supplying D1.7 million, and several Tunisian banks and other financial groups an additional D0.5 million.

Lead.—In 1963 Tunisian mines produced 21,917 metric tons of concentrate assaying 63.0 percent lead, compared with 22,048 tons assaying 61.5 percent in 1962. Production by the four companies active in 1962 follows:

Company:	Mine	Production, 1962 (metric tons)
Union Minière de Tunisie	Djebel Semene	5,000
	El Grefa	5,741
Société Nouvelle des Mines de Sidi Bou Aoune.	Sidi Bou Aoune	3,900
Société Anonyme du Djebel Hallouf	Djebel Hallouf	5,631
Compagnie Equatoriale des Mines	El Akhouat	1,776
Total		22,048

No lead concentrate was exported; except for the Djebel Hallouf production it was smelted in the 25,000-ton-per-year plant of Fonderie de Megriné, an affiliate of the French Penarroya Co., at Megriné. The Djebel Hallouf production was smelted in the company's 4,000-ton-per-year plant at Souk-el-Khémis. The 1963 production of soft lead by the two smelters was the lowest since 1947; it was partly compensated by the increased output of antimonial lead (reportedly containing 60 percent lead). Although some price improvement took place, highly competitive conditions in world markets limited smelter production. Lead exports through November were 12,323 metric tons, valued at an average of D70.45 per ton (D66.76 for the same period of 1962).

Zinc.—As in 1962, the entire Tunisian output of zinc came from the El Akhouat mine of Compagnie Equatorial des Mines, also a producer of lead. It consisted of 7,936 metric tons of 55 percent concentrate (7,768 tons in 1962). Despite an improved price for zinc concentrate, the country's other producer, the Fedj el Adoum mine of Compagnie Minière de Tunisie, remained closed. Exports of zinc concentrate through November were 7,082 metric tons, all to France; average value per ton was D17.04 (D14.03 in the same period of 1962).

NONMETALS

Phosphate.—Each of the three phosphate-producing companies increased production in 1963. Compagnie des Phosphates et du Chemin de Fer Gafsa (GAFSA), 51 percent Government-owned, produced an estimated 1,620,320 metric tons of commercial phosphate from the Metlaoui, Moulares, and Redeyef mines (1,485,498 tons in 1962). Output of Compagnie Tunisienne des Phosphates du Djebel M'Dilla (CIPHOS), entirely Government-owned, was an estimated 479,361 metric tons (385,037 tons in 1962), all from the M'Dilla mine. Société Tunisienne d'Exploitation Phosphatiere (STEPHOS), also 51 per-

cent Government-owned, contributed the remaining estimated 267,412 metric tons (226,568 tons in 1962) from the Kalaa Djerda mine. The commercial product ranged in grade from 29.8 to 34.4 percent phosphorus pentoxide (P_2O_5). Mining was entirely from underground workings. Output of dry, sorted, crude rock, beneficiated by washing, air separation, or calcination was approximately 30 percent higher than that of the commercial product.

Ore reserves were estimated as of January 1, 1963. Reserves in terms of dry, sorted crude phosphate containing 27.3 to 29.1 percent P_2O_5 totaled 107 million tons, about one-half of which is in the "possible" category. Reserves of the GAFSA mines aggregated 55 million tons; CIPHOS had 38 million and STEPHOS had 14 million.

Production of finely ground rock, known as hyperphosphate and exported for direct application on some types of soils, was 85,700 metric tons (34,521 tons in 1962) and is included in the total commercial production shown in the first paragraph of this section. The hyperphosphate is prepared for market in a plant at Sfax. This plant was formerly operated by the Tunisian branch of Compagnie Nord-African de l'Hyperphosphate. However, on February 1, 1963, this branch was merged with GAFSA, completing the control of the industry by the Government.

Total 1963 domestic utilization of commercial phosphate rock was about 350,000 metric tons. In addition to that ground for hyperphosphate, part of which was exported, larger quantities were consumed in the manufacture of triple superphosphate for export by Société Industrielle d'Acide Phosphorique et d'Engrais (SIAPE) and for domestic use by Société Algerienne de Produits Chimiques et Engrais. Total triple superphosphate production was 137,842 metric tons (146,532 tons in 1962).

Exports of phosphate rock through November were at the annual rate of 1.8 million metric tons; hyperphosphate exports were at the rate of 92,200 tons.

Early in 1963 work began on the new triple superphosphate plant to be constructed and operated at Sfax by the new Tunisian company, NPK Engrais, S.A.T. Total investment is to be D33.6 million, including D14.3 million in share capital, provided by Aktiebolaget Fornade Superfosfatbriker (Sweden), International Finance Corp., and Freeport International, Inc., a subsidiary of Freeport Sulphur Co. The plant is scheduled to be completed by late 1965, and annual capacity is to be 150,000 metric tons from 250,000 tons of phosphate rock.

Sulfur.—Sulfur consumption in 1963 was near the 1962 level, when imports as shown by customs statistics consisted of 5,041 metric tons of unrefined, 431 tons of refined, and 1,218 tons of colloidal. In addition, 47,350 tons were imported by SIAPE.[4]

An official order of May 27, 1963, prohibited the importation of all refined sulfur except colloidal sulfur. Reportedly this measure was to safeguard domestic sales of the Raffinierie Tunisienne de Soufre, operators of the Djebel Djelloud plant near Tunis which produces

[4] Not included as imports in customs statistics, because under a 1954 decree, upon export of a given amount of superphosphate the exporters may obtain a permit to import tax-free sulfur equal in weight to that used to produce the exported superphosphate.

Digitized by Google

about 4,000 metric tons of refined sulfur from imported unrefined sulfur.

The new installation of NPK Engrais S.A.T. at Sfax will include a sulfuric acid plant. This will use sulfur at the annual rate of 50,000 tons to be supplied under contract by Freeport Sulfur, a capital participant in the Sfax facility.

MINERAL FUELS

Coal.—In 1963 coal imports increased to 41,872 metric tons; consumption was 40,741 tons (41,268 tons in 1962). Total energy available was 851,200 metric tons of standard coal equivalent (946,000 tons in 1962). The 1963 coal consumption follows: cement and lime plants, 6,140 tons; foundries, 4,427 tons; railways, 698 tons; and others, 29,476 tons. Coal imports through November increased in value from D7.49 per metric ton in 1962 to D7.70 in 1963.

Petroleum.—France continued to supply a significant proportion (39 percent) of the refined products imported; through November these were at the annual total rate of about 540,900 metric tons. Approximate rate for individual products follow: Gasoline, 76,700 tons; kerosine, 49,900 tons; distillate fuel oil, 131,800 tons; residual fuel oil, 264,900 tons; lubricants, 10,900 tons; and liquefied petroleum gas, 6,700 tons.

The new petroleum refinery at Zarzouna, east of Bizerte, was officially inaugurated on December 14, 1963. This facility, built by SNAM-Progetti, an affiliate of the Italian Ente Nazionale Idrocarburi (ENI), at an estimated cost of about D49 million, will be operated by Société Tuniso-Italienne de Raffinage (STIR) and has a capacity of 1 million metric tons per year, although initial output will be at the rate of 650,000 tons. STIR is capitalized at D2.7 million and is owned in equal proportion by the Tunisian Government and ENI. The refinery is designed to utilize crude of the "Iran light" type, which includes the crude delivered through the La Skhirra pipeline from the Edjeleh field in the Algerian Sahara. Results of an international call for bids for crude supply have not been announced.

Reportedly it is expected that the petroleum treated will be of diverse origins; the crude for the first run came from the Kirkuk field in Iraq. The breakdown of the initial run follows: Light gasoline, 6.5 percent; heavy gasoline, 14.0 percent; kerosine, 5.0 percent; distillate fuel oil, 30.0 percent; residual fuel oil, 42.5 percent; liquefied petroleum gas, 1.0 percent; and losses, 1.0 percent. Expectations were that domestic requirements would soon rise to 600,000 metric tons annually and that the surplus will be exported to Italy for marketing in Europe through the ENI distribution system. Design of the refinery provided for expansion to a 1.5-million-ton capacity.

Continued oil exploration brought no significant discoveries and Tunisia remained a nonproducer, despite its proximity to both Algerian and Libyan fields. Expectations were that six wells would be drilled in 1963. Société de Recherches et d'Exploitation des Pétroles en Tunisia (SEREPT) continued exploration within its 33,475-square-kilometer permit in the extreme south, following the withdrawal of its half-interest partner, Mobil Producing Tunisia,

Digitized by Google

Inc., at the end of 1962. As in preceding years, SEREPT exploited the Cape Bon gasfield in the extreme northeast. Société Italo-Tunisienne d'Exploitation Pétroliere, a joint ENI and Tunisian Government venture, followed up its seismic work in its southern Tunisian holding and began drilling at Garet el Borma near the Algerian border. Conorada Petroleum Corp., Rimrock Tidelands, Inc., and Husky Oil Co., other permitholders, were active in varying degrees. Interest in the offshore possibilities has increased, and in April two French firms, Société Petropar and Société Nationale des Pétroles d'Aquitaine, applied for permits to undertake offshore exploration near Cape Bon and in the Gulf of Gabes.

The Mineral Industry of the United Arab Republic (Egypt)

By Thomas G. Murdock[1]

EXCEPT for petroleum, the minerals industry of the United Arab Republic (Egypt) showed little improvement in 1963. As in 1962, efforts were made to attain self-sufficiency and export the few commodities which can be placed on world markets. Other developments included continued exploration and numerous agreements with foreign firms or companies for technical assistance in the solution of specific problems attending the increase of output or for financial aid in the development of new facilities to provide additional productive capacity.

Less than 2 percent of the total labor force of about 8.2 million was employed in the extractive industries; average employment in 1962 totaled 15,309 (3,958 in mining, 7,256 in quarrying, and 4,095 in crude petroleum production), compared with 12,572 in 1961.

The United Arab Republic (Egypt) continued to rank low as a mineral producer; except for phosphate rock, in which the country ranked ninth in 1963 with slightly over 1 percent of the world total, and small quantities of manganese and titanium minerals, its contribution to world supply was insignificant. Nor do the extractive industries contribute appreciably to the national economy. In 1962 the United Arab Republic (Egypt) gross national product (GNP) was £E1,465 million (US$3,370 million);[2] of this, the mineral industries exclusive of metallurgical plants and petroleum refineries contributed only 1.7 percent, or £E24.4 million (minerals and ores, £E6.9 million; cement and construction materials £E3.2 million; and crude petroleum, £E14.3 million). Sales of domestic steel products were valued at £E7.7 million, and total value of refined petroleum products derived from domestic and imported crude was £E80.4 million.

Further nationalization of the industry took place during 1963, and steps were taken to improve the raw material supply for making steel. Plans were announced for further infrastructure developments to decrease further the dependence upon imports and process some by-

[1] Mining engineer, Division of International Activities.

[2] The U.A.R. monetary unit is the Egyptian pound (£E); since May 7, 1962, the International Monetary Fund parity rate has been £E1=US$2.30 (US$1=£E0.4348). Previously (since 1955), exchange was £E1=US$2.8715 (US$1=£E0.3483).

Digitized by Google

products which could not be sold without further processing. Critical shortages in some commodities developed during the year, and increased imports of these became necessary. Foreign markets for several commodities showed indications of expansion by yearend.

GOVERNMENT POLICIES AND PROGRAMS

By a sweeping nationalization decree (law 72), all of the remaining private investment in mining companies was taken over by the Government of the United Arab Republic (Egypt) in August. The new law also terminated all private prospecting and mineral exploitation rights. Thus the United Arab Republic (Egypt) has taken a course in its mining industry different from that taken in the petroleum industry, in which a reduced amount of private and foreign investment has been tolerated and foreign private interests have been encouraged to invest. The newly nationalized mining companies include National Gypsum & Plaster Co., Tobia Contracting & Mining Co., El Ballah Gypsum & Plaster Co., Egyptian Abou Hol Gypsum Co., El Quannam Gypsum Co., Egyptian Metal Industries Co., Elba Mining Co., and Minerals Processing Co.

The Government continued to tighten its control of trade. Previously, under the import regulations promulgated in July 1961, importing was done by 15 Government trading firms, by any Government agency or department, or by privately owned factories and industrial organizations that required equipment or raw materials for their own use. A new law of September 4, 1963, limited importing of commodities to Government bodies. Presidential decision law No. 87 excepted bunkering from the provisions of law 129 of 1962, which stipulate that no company shall be allowed to continue supplying or servicing transiting maritime vessels unless the Government owns at least a 25-percent interest.

On June 29, an Investment Guarantee Agreement was signed between the United Arab Republic (Egypt) and the United States. As a result, new U.S. investment in Egypt can be guaranteed against inconvertibility, confiscation, and war losses. In June the Government of the United Arab Republic formally ratified the country's association with the General Agreement on Tariffs and Trade (GATT), provisionally agreed on in Geneva in November 1962.

The Government mineral agencies continued exploration during the year and the reports of 17 field parties were completed. This work included investigation of the Abu Swail copper occurrence and of lead and zinc at Gebel el Rusas. New discoveries include a gold occurrence at Gebel Ashour in the Eastern Desert. Official announcement was made that self-sufficiency had been attained in marble, zircon, rutile, and glass sand.

SOURCE MATERIAL

Information on other than the main sectors of the minerals industry is scant and mainly limited to a few, often unconfirmed, newspaper accounts giving only fragmentary data. Production statistics from different sources are sometimes contradictory and are not available

Digitized by Google

for some items. In the absence of complete foreign trade statistics covering 1961 and 1962, publications of the Central Bank, giving data for major commodities only, have been used. No available trade data completely itemized trade by countries.

PRODUCTION

Trends in output of the minerals and metals produced in the United Arab Republic (Egypt) have not followed a uniform pattern. Steel production has increased only slowly because operating difficulties have prevented output from reaching the level of plant capacities. Growing competition on world phosphate rock and manganese ore markets has adversely affected output of these commodities. Crude petroleum and refinery products output have shown spectacular gains. Production of building materials has roughly paralleled the growth

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963

in cement production, but exact quantitative data on production of other construction materials are not reported. In 1962, however, the total value of production by the building materials and ceramic industries was £E23.4 million (£E21.4 million in 1961 and £E8.4 million in 1952).

TRADE

Complete detailed data on mineral and metal trade are not available for any year since 1960, when imports of these were valued at £E43.3 million and exports at £E9.2 million. Recorded 1961–62 values for major commodities, accounting for at least 85 percent of the trade in both directions, indicate imports were valued at about £E38.5 million in 1961 and £E50 million in 1962; corresponding extrapolated figures for exports were approximately £E12.8 million and £E18.8 million, respectively. For the first half of 1963 trade in these major commodities was at the annual rate of £E32.5 million for imports and £E19.7 million for exports. Based on comparable rates for the same period of 1962, these represented increases of 40 percent and 35 percent, respectively; however, based on the 1962 experience, this growth was not to be expected for the entire year. In 1962 mineral trade accounted for 17 percent of all imports and 12 percent of all exports.

Fuels consistently have comprised the greatest part of the mineral trade in both directions, and in 1962 crude petroleum imports alone were valued at £E20.0 million and exports at £E11.1 million. In that year the value of major fuel items imported was 59 percent of the mineral imports and 79 percent of the exports. Imports of major crude and semimanufactured metals were valued at £E20.0 million, and exports of manganese ore, the only major export item of the general category, amounted to £E1.0 million. The value of nonmetallic imports was £E1.6 million in 1960, the latest year available. In 1962 the exports of cement and phosphate rock combined were valued at £E2.9 million (4.4 million in 1961).

The U.S.S.R. was the principal source of the 1962 imports, supplying 22 percent of the total, and amounting to £E11.2 million (31 percent and £E13.5 million in 1960).[3]

Imports from other Communist countries (except Yugoslavia) totaled £E9.3 million, or 19 percent, in 1962. Imports from the United States were valued at £E1.5 million, 3 percent of the 1962 total; they consisted of lubricating oil and steel sheets and plates.

Italy was the chief recipient of 1962 mineral and metal exports, with £E8.4 million (45 percent). Other Western European countries were consigned exports valued at £E3.0 million; the Communist countries (except Yugoslavia) received only £E1.0 million. Exports to the United States were £E1.8 million worth of crude petroleum.

Of total 1962 trade with the United States, minerals accounted for 2 percent of imports and 19 percent of exports.

[3] Available trade statistics do not indicate fully the countries of origin and destination for commodities covered; thus trade with countries here shown is only that listed for some individual items; additional trade with these may be included in undistributed totals, so values here shown are minimum ones.

COMMODITY REVIEW

METALS

Iron and Steel.—The Egyptian Iron & Steel Co. integrated steel plant at Helwan, 17 kilometers from Cairo, continued operations at approximately the level of 1962, when output was 157,294 metric tons of Thomas steel ingots and 30,342 tons of electric steel ingots. The plant, with an output capacity of 315,000 metric tons, was still about 40 percent below that figure.

The difficulties attending the production of 42 to 44 percent iron ore from the Aswan mines and of transporting the ore to Helwan, 900 kilometers away, have remained acute. Although production for the year ending June 30 was 500,000 metric tons, 9 percent above that of calendar 1962, the supply was still precarious and imports of ore from Morocco began in the second quarter. Accordingly, the project to exploit the higher grade deposits near Baharia, an oasis in the Western Desert, where reserves reaching 48 percent iron total at least 250 million metric tons, received attention during 1963. In February it was announced that the Swedish firm of Svenska Enterprenad, A.B., had been engaged to undertake an engineering survey of the deposits and plan mine layout and facilities. In March, Aereo Service Corp. of Philadelphia began work on an economic feasibility and engineering survey for a railway link to connect the deposits with the existing line about 200 kilometers to the east.

In January, the U.S. firm of Koppers International signed a 5-year contract to provide technical assistance to the U.A.R. steel industry, the firm will first endeavor to increase production and efficiency at the existing Helwan plant and later plan expansion there. Operation at full capacity has been impossible because of deficiencies or omissions in equipment and shortage of spare parts. Although total investment in the integrated works, as reported in 1963, was £E26 million, estimates were that additional expenditure of £E5.1 at mines and plants was required. Facilities needed included a fourth Thomas converter, additional cranes, and modifications and extensions to buildings. In 1962 rolling-mill input was 175,000 metric tons, resulting in 142,000 tons of marketable products, about one-half of which were sold as blooms. The target for the improvement program is the rolling of 269,500 tons of ingots and rolling all blooms into sections, plates, or sheets.

Equipment for injecting fuel oil into the blast furnace was being installed at yearend; this injection, at the rate of 150 kilograms of fuel oil per metric ton of pig iron, was expected to reduce coke requirements by 30 to 40 percent. Construction was started on two additional soaking pits and a finished-products storage yard.

New monthly production records of 20,442 metric tons of pig iron and 19,864 tons of steel ingots were established in September; previous highs were 19,700 and 18,907 tons, respectively. The labor force at Helwan was still high at the beginning of 1963, totaling 6,640 workers, compared with 3,950 in 1960. Early in the year announcement was made of an agreement to ship 15,000 metric tons of U.A.R. steel to Italy, the first sale made to a European country.

Digitized by Google

Increased production of pig iron was reflected in the lower imports of pig iron and ferroalloys, 18,300 metric tons in 1963. Imports of rolled-steel products were also below the 1962 level, amounting to 96,800 metric tons.

In September a group of Bulgarian technicians came to Cairo to discuss plans for building an 8,000-metric-ton-per-year plant to produce ferrosilicon and calcium carbide at Aswan; only Bulgarian equipment will be used.

Manganese Ore.—The decreased activity in 1963 was reflected in the lower volume of ore exports; only 24,600 metric tons, including some ore with less than 35 percent manganese, had been shipped through June. The downward trend of previous years continued because active competition made difficult the marketing of Egyptian ores, the greater part of which are low grade. Production was limited to the Sinai Manganese Co. mines in the Umm Buqmah areas of Abū Zanimah district. In 1963 this company's capital was raised from £E0.4 million to £E8.0 million. Plans have been announced to build a ferromanganese plant at Abū Rubies; the company also proposed to diversify its activities through the production of gypsum and kaolin.

Thorium and Uranium.—In April a U.A.R.-Yugoslav agreement for scientific cooperation in the peaceful uses of atomic energy was signed in Cairo; the agreement emphasized cooperation in geological and technical research on radioactive minerals. The British consulting firm of Kennedy & Duncan completed its feasibility study of two nuclear powerplants for the U.A.R. Government. Following radiometric air reconnaissance in 1962, the Egyptian Atomic Energy Establishment (AEI) carried out extensive field investigation of anomalies found and reportedly confirmed the occurrence of radioactive minerals at Kossier on the Red Sea coast and in the Qatrari Hill near Fayoum. AEI announced plans to build a plant at Inchass, the site of the installation of their experimental reactor; this plant is to produce radioactive elements from the monazite recovered in the Alexandria plant of the Egyptian Black Sands Co.

NONMETALS

Cement.—The growing local demand resulting from the expanded construction activity continued in 1963, raising consumption above the 1962 figure of 1,856,000 metric tons; the exportable surplus again declined and through June only 93,400 tons were exported. A serious shortage developed during the latter part of the year owing to the 2,000-ton daily shipments to the Aswan Dam. By October the industry was 250,000 tons behind in its deliveries, and to ease the situation, orders were placed in Poland. A contract was signed with East German representatives for the construction of a 200,000-ton-per-year extension to the plant of the Alexandria Portland Cement Co. The recent addition of a new unit by this company accounted for most of the 1963 increased output. In August, law No. 85 added the National Cement Co., operating the slag cement plant at Helwan, to the list of companies in which private ownership was limited to £E10,000; ownership of all shares above that amount and supervision of the company were transferred to the Egyptian Public Organization for Building and Refractory Materials.

Digitized by Google

Phosphate Rock.—During the year there was some revival of the phosphate industry; exports through June totaled 190,900 metric tons, more than in all of 1962. This was mainly due to renewal of exports to India, formerly a principal customer, which took only 6,000 tons in 1962. In 1963 the Nasr Phosphate Co. capital was raised from £E1 million to £E3.6 million, to expand annual production from 200,000 tons to 750,000 tons. That of the Sagafa Phosphate Co. was raised from £E0.1 million to £E2.8 million for increasing output from 100,000 tons to 330,000 tons. Both companies planned to improve beneficiation facilities. A West German consortium concluded a technical assistance contract with the Egyptian General Mining Organization, the governmental agency in charge of all mining enterprises, under which the German firms will explore the phosphate rock deposits in the Harawein region. An order was placed with a German firm for the construction of a superphosphate plant in Upper Egypt.[4] The production of superphosphates by Société Financière et Industrielle d'Egypt and Abū Zsabal et Kafrel Zayat Fertilizers & Chemical Co. continued in 1963; in 1962 these companies reported a combined output of 163,000 metric tons, and their consumption of phosphate rock accounts for part of the difference between production and exports.

Potash.—The Egyptian press reported that U.A.R. scientists discovered sizable deposits of potash in the areas being prospected for petroleum along the Red Sea coast.

Salt.—The capital of the Government's Nasr Salt Works, which produces salt by solar evaporation of sea water in several localities, was increased from £E0.4 million to £E2.5 million, to increase annual output to 850,000 metric tons. Salt exports in 1962 were 209,000 metric tons (382,000 tons in 1961).

MINERAL FUELS

Coal and Coke.[5]—In 1963 representatives of the U.A.R. 5-Year Plan Organization signed a 4-year contract with the British firm of Powell Duffryn Technical Services, Ltd., for the planning and supervision of work on Egypt's first coal mine, at Maghara in the Sinai Peninsula. The coal deposits, 290 kilometers from Cairo, are of Middle Jurassic age, and occur in two seams ranging in thickness from 0.80 to 2.00 meters. Ash content is 3.8 percent, over 50 percent volatile matter is present, and the coal is cokable. The proposed mine is to have an initial annual production of 120,000 to 150,000 metric tons, most of which will be coked at Helwan. The mine installations and complementary housing and other facilities are to cost about £E2 million. Initial plans call for evacuating the coal by road; however, proposals for building a railway were being considered at yearend.

The byproduct coke plant at Helwan was dedicated in December; actual production was scheduled for early 1964. This installation, constructed under the 1958 Soviet industrial credit agreement at a reported cost of £E11 million (£E4 million was as U.S.S.R. machinery

[4] Canadian Mining Journal (Gardenvale, Quebec). V. 85, No. 2, February 1964, p. 164.
[5] Mining Journal (London). Egypt's First Coal Mine. V. 261, No. 6691, Nov. 15, 1963, p. 465.

Digitized by Google

and equipment), has a capacity of 300,000 metric tons per year and will employ 600 workers. Coke oven gas will amount to 140 million cubic meters per year and will be sold to a nearby fertilizer plant. Other byproducts are expected to be valued at £E270,000 per year. Production costs are estimated at about £E14 per metric ton (compared with about £E11 for imported coke).

Imports of coal and coke through June were only 98,800 metric tons, well below the rate of preceding years. The decrease was due to the increasing substitution of oil fuels and to a temporary buildup of coal stocks for making coke at Helwan.

Petroleum.—The United Arab Republic (Egypt) continued to try to attract investment by foreign oil companies in petroleum concessions on the basis of 75–25 percent split in profits in favor of the Government. Offshore concessions were offered in the Gulf of Suez and land concessions were offered in the Nile Delta, Western Desert, and North Sinai. Phillips Petroleum Co. obtained a 96,000-square-kilometer concession in the Western Desert on the 75–25 eventual profit-sharing basis. The Italian Ente Nazionale Idrocarburi (ENI) signed similar oil concession agreements for both the Delta and Suez Gulf areas. A new law authorized both Shell and Compagnie Orientale des Pétroles d'Egypt (COPE), a joint ENI-U.A.R. company, to continue for another 25 years as U.A.R. joint stock companies.

The Petroleum Cooperative Society (COOPS), largest single retailer of petroleum products, was converted into a joint stock company. COOPS lost its concession leases to the General Petroleum Co. (GPC) and became a general marketing company, while GPC gave up marketing to engage exclusively in exploration and production of crude. The marketing elements of GPC were combined with the Egyptian Independent Oil Co. to form a new marketing organization, the Arab Co. for Oil Distribution.

Estimated oil reserves of 100 million metric tons at the beginning of 1963 were announced. COPE concessions were believed to contain 86 percent of the total; Al Nasr oilfields held 8 percent and GPC, 6 percent. During most of the year exploratory drilling continued at a lively pace but without significant results. In the Belayim marine field seven wells were in production in 1963 and the eighth was completed at a total depth of 3,008 meters. Plans were announced to drill ultimately 29 wells in this field. By August exploration at both Rahmi and South Gharib had not resulted in a commercial discovery. Efforts to develop a new marine field at Baba were unsuccessful, and the offshore rig was returned to Italy. The Italian offshore rig at Belayim marine was the only one in U.A.R. waters at yearend; however, the Petroleum Organization began the construction of islands in the Gulf of Suez, through the use of earth fill, to be used as offshore drilling platforms.

A Cairo-Helwan pipeline and a butane gas packingplant at Mostered (Cairo) were completed in late 1963. The 30-centimeter pipeline has an annual capacity of 1.8 million metric tons and supplies various installations in the Helwan area. Work was continued on the £E27 million petroleum coke plant being built at the Government refinery at Suez by Compagnie Tecnica Italiana Petroli, and completion was scheduled for early 1964. Work was begun on the lubricating oil

Digitized by Google

plant at the Suez refinery; this £E6 million U.S.S.R.-sponsored plant is scheduled to go on stream at the end of 1964 and to produce 70,000 metric tons of lubricants per year, which should meet U.A.R. needs for ordinary lubricants, although special ones will still be imported.

Plans to provide additional refinery capacity of 1 million metric tons were announced in July; this would be installed at the Alexandria-Mex refinery of Société Egyptienne de la Raffinage et Commerce des Pétroles, where an earlier extension of this size installed by Czechoslovakian interests began operations on October 28, 1962. Plans were formulated to establish a petrochemical complex at Alexandria or Suez, to use surplus naphtha being produced by the U.A.R. refineries. Consumption of this naphtha has lagged behind that of other petroleum products because of the high price set by the Government. The proposed plant would process 120,000 metric tons of naphtha yearly into various products. Several U.S. firms have indicated interest in participating in this venture.

Total employment in the entire petroleum industry for 1963 was reported at 23,173. Production of crude in June was at the rate of 5.8 million metric tons annually. The appreciable increase in output from the Belayim offshore field, following first production there in 1962, accounted for much of the gain. The Belayim land field continued to be the principal producer, with 49 percent of the June total.

Contracts called for imports of 3.9 million metric tons of crude during 1963, to be furnished by Caltex, Shell, and the Soviet Union. The supply contracts were tied in with provisions for the suppliers to buy 600,000 metric tons of Egyptian crude and 220,000 tons of products. Italy was expected to take 2.5 million metric tons of crude and 8,000 tons of butane alone. Expectations were that the United Arab Republic would be self-sufficient in products during 1963. Plans were to refine 6.5 million metric tons of domestic and imported crude; with the supplies contracted for, the expected increase in local production, and new refinery capacity, this goal appeared to be within reach. Data on trade for 1963 are not available, but for the first half of the year a favorable balance of oil trade of £E2.4 million was reported. For this period imports of crude were 629,600 metric tons; exports were 1,533,000 tons. Other imports consisted of 30,000 tons of lubricants and 53,700 tons of diesel and other fuel oil. Exports were 63,500 tons of gasoline and kerosine, 321,800 tons of diesel and other fuel oil, and 5,600 tons of other products.

The 1962 consumption of refined products consisted of gasoline 253,000 metric tons; kerosene 817,000 tons; distillate fuel oil 925,000 tons; residual fuel oil 2,394,000 tons; asphalt 139,000 tons; and butane 30,000 tons. Indications are that in 1963 consumption of fuel oils increased.

The Mineral Industry of Upper Volta

By Thomas G. Murdock[1]

THE Republic of Upper Volta (Haute Volta), a former territory of French West Africa until it became independent on August 5, 1960, has been the scene of various small-scale mining activities for many years. However, it was only recently that the mineral deposits were systematically investigated, with the result that gold production from a single mine has become of significance as an export item. A number of other metals have been discovered but so far there have been no definite reports of any which are likely to be suitable for economic exploitation. The year 1963 produced no new developments other than the granting of rights for diamond exploration and announcement of plans for production of ornamental granite; gold production apparently showed a slight improvement. For a population of 4.6 million, and with animal husbandry as the chief economic activity, Upper Volta continued to have only limited need for metal and mineral imports. The value of principal imports of these increased slightly in 1963 and was over twice that of gold exports, thus leaving an important trade deficit in metals and minerals.

In 1962 the gross national product (GNP) was CFAF44,835 million (US$183 million)[2]; the gold production at world price was valued at CFAF341 million, only 0.8 percent of the GNP.

Personnel engaged in gold mining consisted of about 600 African workers and about 20 Europeans, a small fraction of the economically active labor force.

GOVERNMENT POLICIES AND PROGRAMS

No new mining legislation was reported during the year. The government favors private enterprise and has passed special legislation to encourage foreign firms to invest in Upper Volta. Nevertheless investment opportunities continued to be limited. A French-sponsored industrial survey made in 1962 indicated that the most promising opportunities were in the livestock field. A fertilizer plant was considered but nothing came of this as without raw materials and with a high cost of transportation, it would be uneconomic. Late in 1962 announcement was made of West Germany financing to the extent of CFAF400 million for construction of a cement plant, but no record of any progress on the project is available. Following its initial 1963 session, Upper Volta's Council of Ministers announced that the 5-year development plan, scheduled for January 1, implementation, would not be put into effect. Instead a decision was made

[1] Mining engineer, Division of International Activities.

[2] African Financial Community (CFA) francs are used in Upper Volta. The exchange rate is US$1=CFAF245 (CFAF1=US$0.0040816).

Digitized by Google

to adopt a 2-year interim plan while the longer range document is redrafted. The interim plan was to concentrate on certain sectors rather than the economy as a whole but should fulfill the more important goals of the former plan. Aside from the stable currency, Upper Volta's finances remained in a precarious position; the country has had a continuing trade deficit and economic progress has been slow. Without strong French support, the country's administrative and economic superstructure would be difficult to sustain.

Mineral prospecting and investigations financed by the national budget with French and other assistance were continued under an integrated plan covering the 1963–67 period and embracing work costing CFAF2,500 million.[3] In 1962 the French Bureau de Recherches Géologiques et Minières maintained 13 parties in the field; their work included an investigation of the anomalies resulting from an earlier aerial geophysical survey covering 37,000 square kilometers. The Upper Volta Directorate of Geology and Mines had 3 parties in the field in 1962, engaged in detailed geological mapping and exploration of alluvial gold deposits.

SOURCE MATERIAL

Some information on production and developments was supplied by the U.S. Embassy in Ougadougou, however, English and French publications provided most of that contained in this country review.

PRODUCTION

Recorded production of metals and minerals in Upper Volta consists only of gold. The 1959 gold output was 4,019 troy ounces, declining in 1960 to 1,161 ounces. Production in these years was largely the result of development at the Poura mine; output increased to 15,497 ounces in 1961. With additional working faces exposed and the recovery facilities functioning normally, production was expanded to 39,770 ounces in 1962 and an estimated 45,000 ounces in 1963. Data on production of building materials are not available; indications are that except for cement and lime, Upper Volta is self-sufficient in building materials.

TRADE

Little data are available on the metals and minerals trade of Upper Volta. Exports apparently were limited to gold and in 1962 reportedly accounted for 20 percent of the total on basis of value. All exports were valued at CFAF1,945 million by published statistics, gold exports of 45,364 ounces are indicated; the value of these at the world price of CFAF8,575 per ounce was CFAF389 million.[4] Small quantities of metals and minerals of nondomestic origin may have been exported to neighboring countries, and some scrap metals have been exported to Europe. Principal 1962 imports of metals and minerals

[3] Mining Journal (London). Annual Review, 1964. June 1964, p. 203.
[4] Exports of all gold produced in 1962 would have been worth CFAF341 million at the world price, 17.5 percent of all exports. Thus indications are that 1962 exports may have included 5,594 ounces from earlier production or that the reported 20 percent was an approximation.

Digitized by Google

had a total value of CFAF764 million, 9 percent of all imports; in 1961, the total was CFAF690 million (exclusive of nonferrous metal imports which were CFAF34 million in 1962), 10 percent of all imports.

Destinations of gold exports are not indicated by statistics nor are they reported in the literature; a part of the gold is recovered from the treatment of amalgamation rejects in Sweden. Neither are data available on the sources of the metal and mineral imports; as France supplied 52 percent of all 1962 imports, they probably came mainly from that country. The European Economic Community, of which Upper Volta is an associate member, supplied an aggregate 57 percent of the total and the United States supplied 4 percent.

The 1963 gold exports had an estimated value of CFAF386 million, assuming that the quantity equaled the production. Based on total imports through November, the 1963 imports of metals and minerals were valued at approximately CFAF805 million, if they were again 9 percent of the total.

TABLE 1.—Principal imports of metals and minerals [1]

Commodity [2]	Quantity (metric tons)		Value (millions of CFAF)	
	1961	1962	1961	1962
Metals:				
Iron and steel [3]	6,881	6,149	262	260
Nonferrous	(4)	[5] 153	(4)	[5] 34
Nonmetals:				
Cement	22,009	27,106	92	110
Salt	5,251	7,432	37	71
Mineral fuels:				
Petroleum refinery products [6]	31,232	29,734	[7] 299	[8] 289

[1] Data on source are not available; France was undoubtedly the leading supplier.
[2] Data on other items imported are not available, nor is a further breakdown possible.
[3] Mostly rolled products but may include small quantities of pig iron.
[4] Data not available.
[5] Includes: Aluminum 44 tons; copper 102 tons; and lead 7 tons.
[6] Includes 5,755 tons of kerosine in 1961 and 4,997 tons in 1962; and, 182 tons of liquefied petroleum gas in 1961 and 189 tons in 1962.
[7] Includes CFAF128 million of gasoline and CFAF43 million of distillate fuel oil.
[8] Includes CFAF104 million of gasoline and CFAF39 million of distillate fuel oil.

COMMODITY REVIEW

METALS [5]

Gold.—Upper Volta's gold production came entirely from the Poura mine, 175 kilometers southwest of Ouagadougou, and operated by Société des Mines de Poura, owned jointly by a private French company and the French Government's Bureau des Recherches Géologiques et Minières (BRGM). The deposit consists of two veins in greenstone, only one of which was worked in 1963, when ore production came mainly from the 147- and 207-meter levels and hoisting was through two shafts. The lower level had a drift extending about 1,500 meters. Sinking of a shaft to the 327-meter level was completed, and exploration here revealed vein continuation. In 1962 about 81 percent of the gold recovery was by amalgamation in the plant at

[5] Mining Journal (London). V. 261, No. 6683, Sept. 20, 1963, p. 257. Mines et Metallurgie (Paris). No. 3,582, Mar. 1964, p. 131.

Digitized by Google

the mine and the remainder came from amalgamation rejects treated in Sweden. Average yield from all ore treated in that year was 0.57 ounce per ton. The 1963 target was 58,240 ounces at an average grade of 0.45 ounce per ton, but indications are that actual output was about 23 percent lower. In mid-1962, reserves were estimated to total 416,000 tons of exploitable ore, with another 152,000 tons in a neighboring outcrop which, for technical reasons, must await the completion of the other working. Ore extraction in 1963 apparently was at the rate of about 11,000 tons per month. Exploration indicated that reserves can be held at about the existing figure, but no increase is foreseen. Some surface prospecting was done in 1962, but without success. Drilling was scheduled to be undertaken near Poura in 1963 if the equipment on order arrived in time.

Manganese.—No progress was reported on the development of the 52-percent manganese ore deposit at Tambaou, near Markoye close to the Niger frontier. Although reserves total at least 5 million tons and are placed at 10 million by some sources, their richness does not overcome the disadvantage of the remoteness of their location, almost 1,000 kilometers from the sea. In 1963 the BRGM investigated manganese occurrences in the Tiere, Soukoura, and Kaya-Koto regions.

NONMETALS

Diamond.—The Upper Volta Government awarded the West African Selection Trust, Ltd., a British firm, the right to explore for diamond in 240,000 of Upper Volta's 274,000 square kilometers. The right was granted for 1 year beginning January 1, 1964, and can be renewed for 2 additional years. A subsidiary, Selection Trust Exploration Ltd., will do the actual exploration, and the commitment calls for annual expenditures of about CFAF15 million. Indications of diamond have been found in the region near the Ghanaian border.

Granite.—In October, a 35-ton load of eight granite blocks from Kombissiri, 48 kilometers southwest of Ouagadougou, was sent to Carrare, Italy, for testing. The tests are expected to confirm University of Pisa reports that Upper Volta's granite is among the best in the world. The deposits are reported to be practically inexhaustible and to come in a rich range of 10 different colors. Quarrying on a commercial scale was expected to start in early 1964 after the importation of special equipment.[6]

MINERAL FUELS

Petroleum.—Because of unfavorable geological conditions, Upper Volta has remained one of the few regions of Africa where oil exploration has not been carried out. Imports of petroleum refinery products continued to come in by rail from Abidjan, Ivory Coast, from oversea suppliers. Upon the completion of the refinery at Abidjan, scheduled for 1965, this facility will provide most of Upper Volta's requirement. Imports through November 1963 were at the annual rate of 31,200 tons, roughly the same as the 1961 imports and 5 percent above those of 1962.

The Mineral Industry of Bahrain

By F. L. Klinger[1]

CRUDE OIL refining continued to be the foremost industry of Bahrain in 1963. This island, the largest of a group 30 kilometers off the Saudi Arabian coast, is the site of the first petroleum discovery in the Persian Gulf and in the Arabian peninsular region. The island's only oilfield was discovered in 1932; exports of crude began in 1934 and the refinery was built in 1936. Although its crude oil has been less than 1 percent of annual Middle East output in recent years, Bahrain has been an important refining center for many years, processing a substantial portion of Saudi Arabian petroleum as well as all local production. The Bahrain refinery annually accounts for 17 percent of the petroleum products produced in the Middle East and 25 percent of the exports.

Bahrain's mineral resources consist of oil, gas, and basic construction materials. Petroleum production and refining are the important mineral industries and contribute most of the national income by payments for taxes, wages, and local services including construction and material supply. The petroleum industry has supported a large share of local business and extensive indirect employment, and its early establishment also helped Bahrain to strengthen its position as a trading center in the Persian Gulf. The country's entrepôt trade produces about 20 percent of Government revenue, and Bahrain is somewhat less dependent on the petroleum industry than are the neighboring States to the west.

In 1963 the petroleum industry contributed about US$32 million to the Bahrain economy. Revenue from petroleum accounts for about 80 percent of all Government revenue and most foreign exchange earnings, and is mainly derived from the Bahrain Petroleum Co., Ltd. (Bapco), owned jointly by Texaco Inc. and the Standard Oil Co. of California. The Government levies an income tax of 50 percent on the net profits of Bapco derived from the sale of products refined from crude oil produced in Bahrain or imported for processing in Bahrain. Bapco is the sole petroleum concessionaire and employed 5,360 Bahraini personnel in 1963.

PRODUCTION

Petroleum production from Bahrain has averaged about 45,000 barrels per day for the past 5 years. In December 1963, Bapco announced an increase in production of 1,000 barrels per day, and

[1] Foreign mineral specialist, Division of International Activities.

Digitized by Google

additional increases were expected in 1964. The increase in productivity resulted from detailed physical studies of the Bahrain field, new techniques of well stimulation, and the completion of additional wells. All petroleum production was processed at the Bahrain refinery.

Refinery throughput in 1963 averaged more than 229,000 barrels per day. This was 6 percent less than in 1962 but was still the second highest annual output on record. The feed consisted of approximately 79 percent of Saudi Arabian crude, 20 percent Bahrain crude, and 1 percent of other stocks. Principal refinery products, in percent of total production, were residual fuel oil (42), diesel oil (25), gasoline and naphtha (20), and kerosine and jet fuel (12). The gross value of refinery production in 1963 was estimated at US$217 million (based on price quotations at Ras Tanura).

TABLE 1.—Production of crude oil and petroleum products

(Thousand 42-gallon barrels)

Commodity	1959	1960	1961	1962	1963
Crude petroleum	16,473	16,500	16,444	16,446	16,503
Refinery products:					
Gasoline	14,046	14,329	13,577	16,815	16,361
Jet fuel	2,658	2,876	4,715	5,972	5,138
Kerosine	6,019	6,445	4,920	4,532	4,228
Distillate fuel oil	15,777	16,870	18,412	20,410	19,804
Residual fuel oil	26,082	29,620	31,483	34,827	33,362
Other	631	1,266	1,150	379	187
Total refinery products	65,213	71,406	74,257	82,935	79,080
Refinery fuel and loss	3,931	4,725	5,632	5,745	5,608
Total refinery throughput	69,144	76,131	79,889	88,680	84,688

TRADE

Petroleum.—Bahrain normally exports only refinery products. Exports in 1963 totaled 78.95 million barrels including 5 million barrels of bunker fuel. An additional 390,000 barrels of petroleum products were marketed locally.

Bahrain imported more than 66 million barrels of crude petroleum from Saudi Arabia in 1963. Most of this crude entered the country from Dhahran through two 12-inch, 54-kilometer pipelines, and additional shipments were made by tanker. The pipelines have a combined throughput capacity of about 200,000 barrels per day.

Other.—Limited information suggests that the value of Bahrain's trade exclusive of petroleum in 1963 was not appreciably changed from 1960–61 levels. The value of imports was estimated at US$60 million, and reexports at US$21 million. The value of mineral and metal trade probably did not exceed 5 percent of either figure. Statistics for 1957–61 indicate annual imports of about 50,000 tons of cement and 1,200 tons of metal and nonmetal manufactures. About 50 percent of reexports are destined for Saudi Arabia, with the remainder going to Qatar, the Trucial Coast, and Iran. Large quantities of gold bullion are occasionally imported, as in 1957 when imported gold was valued at more than US$10 million.

[1] Most if not all crude oil imports are from Saudi Arabia. Data on origin of other imports, and destinations of exports, are not available.

COMMODITY REVIEW

MINERAL FUELS

Petroleum.—All crude oil produced in Bahrain has come from a single onshore field in the southern part of the island. The major portion of the field's production is 33° API gravity oil from Cretaceous formations at depths of 2,000 to 2,600 feet, although there is some production from deeper zones. Petroleum reserves at the end of 1962 were estimated at 240 million barrels.

Considerable work was done by Bapco in 1963 to develop additional petroleum reserves and to increase the rate of production. A program of detailed geophysical and stratigraphic studies, intended to suggest new drilling locations, was continuing at the end of the year. Four 1,500-foot wells were drilled near Sitra for indications of oil-bearing structures but yielded negative results. Three exploration wells were drilled, two of which were completed as commercial producers. The third exploration well, drilled to a depth of 5,858 feet to test productivity of the Fadhili zone, found oil but not in commercial amounts. Six development wells were completed, five as triple-zone producers and one as a dual-zone well. By the end of the year the number of oil-producing wells was 170.

Offshore drilling northwest of Bahrain by the Arabian American Oil Co. in 1963 discovered oil at Abu Safah, located in an area covered by a profit-sharing agreement between Bahrain and Saudi Arabia, and delineation drilling began in September. Previously, Bapco had drilled a 13,993-foot dry well in 1961 on Fasht al-Jarim north of Bahrain, and another dry well southeast of Bahrain in 1962. The latter well was located on Hawar Island and was abandoned at a depth of 8,241 feet.

At the refinery, several large process installations were modified during 1963 to increase production of high-octane gasoline, diesel oil,

Digitized by Google

and kerosine. Shipping storage capacity was increased by 230,000 barrels.

Shipping facilities completed during the year included a new sea-line manifold, electronic equipment for introducing additives to finished products, and a coastal tanker wharf for bunkering vessels up to 1,000 deadweight tons.

Natural Gas.—Natural gas was used for pressure-maintenance in the Bahrain field, and as fuel for the Government-owned power station. Field injection is normally accomplished through six injection wells, supplied by five production wells. In 1963 gas injection into the main limestone reservoir was suspended for a trial period, although injection was continued into the siltstone reservoir, and only one injection well, supplied by one production well, was in service in 1963.

The capacity of the dehydrating plant for gas supplied to the power station was expanded to 20 million cubic feet daily in 1963.

The Mineral Industry of the Republic of Cyprus

By Anton W. T. Wei [1]

PRODUCTION of pyrites, largely as a coproduct with copper, continued to be the Republic of Cyprus' only mineral output of world significance. In terms of sulfur content, pyrite output represented over 5 percent of the world's total, and the country ranked sixth among its leading producers of sulfur in pyrites. Domestically, copper remained the most important mineral produced. The Republic's mineral industry as a whole has been important to the country's economy. In 1963 mining and quarrying contributed about 6 percent to the country's gross domestic product of approximately US$267 million.

The Forest Oil Corp., which had been granted an exploration license by the Cyprus Government in 1962, continued seismic work during 1963. Actual drilling, with anticipated depth of about 1,600 meters, was not scheduled until 1964. Under the provisions of the license, which covers more than three-quarters of the island area, Forest Oil was to spend US$4.9 million for exploration over 15 years. The license also provides for exploitation rights for 40 years, renewable for an additional 20 years, with government participation on an equal basis, if oil is found in commerical quantities. The company had carried out geophysical work on the island during 1957–58 under licenses granted by the colonial government.

SOURCE MATERIAL

Information on mineral developments of the Republic of Cyprus was obtained from foreign service dispatches of the U.S. Embassy in Nicosia and the Annual Report of the Cyprus Mines Corp. Background information on the mineral industry was derived from annual reports of the Senior Mines Officer of the Cyprus Government. The country's trade data were obtained from the official publication, "Statistics on Imports & Exports," issued by the Department of Statistics and Research, Ministry of Finance.

PRODUCTION

Overall mineral production of Cyprus in 1963 rose slightly over the 1962 level and was valued at approximately US$25 million. Based

[1] Physical scientist, Division of International Activities.

Digitized by Google

on preliminary information, output of copper concentrates, cupreous pyrite, and cement copper, increased; output of iron pyrite decreased. The internal crisis which began in late December had little, if any, effect on the year's mineral production. Lesser mineral commodities produced on the island were cement, gypsum, chromite, and mineral pigments. Again, Cyprus smelted no metals and produced no mineral fuels.

The Cyprus Mines of the Cyprus Mines Corp., a U.S.-owned company with home offices in Los Angeles, Calif., continued to be the most important mineral producer on the island in 1963. Its Mavrovouni and Skouriotissa operations accounted for over 70 percent of the year's total mine-copper output and about 69 percent of the pyrite output.

TABLE 1.—Production of metals and minerals

TRADE

The contribution of the mineral industry of Cyprus to the country's balance of payments may have been of greater importance than its contribution to the gross domestic product. Despite a decline from the 1962 level, mineral exports in 1963, reportedly valued at about US$21 million, represented 38 percent of the total domestic exports. Statistics on imports for 1963 are not yet available, but mineral imports in 1962 totaled roughly US$18 million, more than 90 percent represented by iron and steel and petroleum products.

COMMODITY REVIEW

METALS

Chromite.—The mining operations of the Cyprus Chrome Co., Ltd., the only chromite producer on Cyprus, remained at a standstill throughout 1963. Presumably the reported chromite output for the year came from the milling of old tailings. Disruption of mining activities was due to a strike by the workers which began in July 1962; normal production was not resumed at the end of 1963 because of low world prices and the lack of sufficient export markets for the mine to operate economically.

Copper and Pyrite.—Despite the near depletion of its ore reserves, the Mavrovouni mine of Cyprus Mines increased its output slightly in 1963 and remained by far the largest copper and pyrite producer on the island. In the meantime, the reactivation of Skouriotissa as an open-pit operation by Cyprus Mines, which began in early 1962, continued throughout 1963. Modification of the flotation concentrator was completed, and construction of a new plant for the recovery of copper and pyrites from old tailings was reported to be 80 percent completed at yearend. During the later months of the year, the eastern section of the Skouriotissa ore deposit was uncovered and 127,000 tons of ore was mined. Skouriotissa was slated soon to replace Mavrovouni as the leading copper and pyrite producer on Cyprus. With the open pit mining of the small Apliki deposit at a later date, Cyprus Mines plans to maintain its current level of output into the 1970's.

NONMETALS

Gypsum.—The United Gypsum, Ltd., with its operations at Kalavasos, remained the largest gypsum producer on Cyprus. However, preliminary information indicates that, as in the past, the "unlicensed quarries" produced the majort part of the island's total 1963 gypsum output.

The Mineral Industry of Iran

By L. Nahai [1]

THE oil industry remained the dominant sector of Iranian mineral industry in 1963; it also continued to contribute significantly to the country's overall economy, providing by far the greatest share of Iranian exports in terms of value and employing more of the country's industrial labor than any other segment of industry. Revenue payments of US$377.6 million and purchases of local currency totaling US$84.7 million by the oil companies in 1963 was equivalent to 83 percent of the Iranian foreign exchange receipts (excluding foreign loans and grants) in the Iranian calendar year ending March 20, 1963. The total revenue payments and local purchases were 18.5 percent more than in the previous year. The oil industry was estimated to have contributed 11 to 12 percent of the gross national product. The high rate of growth of the industry provides borrowing capacity necessary for the rapid expansion of public investment.

Other segments of the mineral industry, although not comparable to petroleum, supplied practically all the country's requirements of building raw materials, as well as modest tonnages of metalliferous ores, principaly lead, zinc, and chromium, for export.

The value of minerals other than petroleum produced in Iran in 1962 (the last year for which data are available) has been estimated as about US$5 million. However, this figure excludes the very large tonnage of clays, limestone, and other stones produced throughout the country for making cement, lime, brick, and building stone.

The Iranian Oil Exploration & Producing Co. and the Iranian Oil Refining Co. (together referred to as the Consortium) employed 18,600 workers in 1963, and the National Iranian Oil Co. (NIOC) employed 12,347 to administer nonbasic operations in Abadan and in the oilfields of the Consortium. NIOC's own production and refinery employees, estimated at 10,000, increased the total for the oil industry to about 40,000, exclusive of distribution and the several hundred employed in the offshore operations of Société Iran-Italienne des Pétroles (SIRIP) and Iranian Pan American Oil Co. (IPAC). By comparison, the total industrial labor force of the country in 1963 was estimated at 200,000. Reliable information on employment in metalliferous mines, clay pits, quarries, and cement plants is not available but probably does not exceed a few thousand.

Iran continued as an important world oil supplier, furnishing 10 percent of the crude and 5 percent of the refinery products of total 1962 world exports and re-exports. Preliminary information indicates that corresponding 1963 figures were 10.8 percent for crude and 4.8 percent for refinery products.[2]

[1] Near East-south Asia specialist, Division of International Activities.

[2] In this calculation, exports to U.S.S.R., Eastern Europe, and mainland China have been assumed at same level as those in 1962.

Digitized by Google

Except for natural gas, much of which is flared, other mineral commodities produced in Iran were not significant in total world supplies.

Successful exploration during the year increased oil reserves. Production unit capacity of the southern oilfields increased, and work started on a second 40-kilometer 30-inch submarine pipeline from Ganaveh on the mainland to Kharg Island.

The program of modernization and streamlining of operations in Abadan continued. Iranian authorities were concerned with the further utilization of natural gas produced with crude and approached the Instituit Français de Pétrole regarding preparation of a feasibility study for utilization of the natural gas including production of petrochemicals.

On April 1, 1963, the NIOC announced that parts of Iranian Petroleum District 1, including parts of Iranian territorial waters and continental shelf in the Persian Gulf, would be declared open effective on or about July 1, 1964. Two areas were described, each extending to the median line of the Persian Gulf. These did not include territorial waters 3 miles from low tide on the mainland nor the island of Lavan and its surrounding 3-mile limit; these areas lie within the Consortium Agreement area.

By the end of July of 1963, the deadline set by NIOC, 8 individual companies and 5 groups of companies totaling 31 companies of American, French, German, Dutch, and Italian ownership had formally declared their interest in the area and were accepted to participate in financing the marine seismic survey of the area. The cost of the survey was to be shared equally by the 13 participating companies and company groups. NIOC concluded an agreement with the Western Geophysical Co. of United States to perform marine reflection seismic surveys in 45,000 square kilometers comprising the areas involved. The survey was started on September 15, and was still in progress at yearend. Areas to be put up for bidding may be 8,000, 4,500, or 3,250 square kilometers, depending on the degree of NIOC participation or nonparticipation.

Diamond drilling of three promising lead-zinc mines, a project of the U.S. Agency for International Development, found high-grade ore reserves and interested foreign capital in the exploration and development of these properties. Two foreign firms were reportedly negotiating with the Iranian mine owners for collaboration and investment.

Favorable results of this exploration drilling led to the initiation of an assistance program for private mines as a part of the technical assistance program for private industry administered by the Ministry of Economics. The Mines Section of the Ministry plans to expand aid in exploration, surveying, mapping, sampling, and appraising of privately owned mines.

A decree of September 8, 1963, established subsidies for export of Iranian ore: 20 percent for iron, lead, manganese, and chromite and 10 percent for zinc ore to be calculated on the basis of the f.o.b. price.

The Geological Survey of Iran, established in February 1962 as a United Nations Special Fund project, continued its activities during the year, but accomplishments to date have not been reported.

Digitized by Google

PRODUCTION

The petroleum industry increased its crude output in 1963, continuing a trend which started in 1955 with the Consortium's operation of the oilfields of southwest Iran. Refinery throughput by the Consortium was about the same as in 1962; 84 percent of the throughput was for export by the Trading Companies as products and 16 percent for the account of NIOC for domestic consumption. There was a small increase in output of refinery products; NIOC increased its gross make of refined products (exclusive of Masjed-e Soleyman topping plant) to 2,294,338 [3] barrels. An important factor in this increase was the contribution of 938,182 barrels from the Alborz topping plant.

Production data for other minerals are not available. Chromite output was adversely influenced by smaller exports, but higher world prices may have stimulated production of lead and zinc. Owing to a business recession, building activities were at a reduced level, and this may have adversely affected output of building raw materials. Stocks of cement at yearend were reportedly 150,000 tons which must have had a depressing effect on the cement industry.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963

[5] Total production, including that flared without use and that used expansively to drive turbines and then flared.

TRADE

Crude oil export established a new record in 1963 and was 15.5 percent above that of 1962. Export of products increased by 2.3 percent. Crude accounted for 79 percent by weight of total petroleum exports,

[3] Excludes product shipped from the Naft-e Shah topping plant which may have been shipped without further processing.

Digitized by Google

compared with 75 percent in 1962. This rise continued a long-term trend of more crude exports to meet the demands of foreign refineries as well as a steady rise in Iranian consumption of petroleum products refined in the country, leaving proportionately less crude for export.

NIOC did not export any royalty crude (12.5 percent of the total) to which it is entitled under the oil agreement with the Consortium but instead elected to accept value at posted prices.

Based on preliminary tanker destination reports, the Consortium reported that its crude shipments during 1963 went principally to Europe (46 percent), followed by Japan (14 percent), Southeast Asia (12 percent), North America (12 percent), Africa (10 percent), and Australia (4 percent). Refined products were shipped to Africa (36 percent), Southeast Asia (27 percent), the Persian Gulf mainly as bunkers (20 percent), Japan (7 percent), Australia (5 percent), and Europe (5 percent).

The NIOC exported about 28,000 tons of products to Afghanistan. The products, consisting mainly of kerosine and gas oil, were trucked from Meshed where the NIOC pipeline terminates.

Mineral exports other than petroleum in the Iranian calendar year ending March 20, 1962, totaled US$4,902,000. In the first 9 months of 1963 exports amounted to approximately 116,500 tons valued at US $2.8 million. Breakdown of the exports for 1963 is not available.

Iran's mineral and metal imports in 1961–62 consisted primarily of iron and steel, some nonferrous metals and industrial minerals, cement, and fertilizer raw materials with a total value of US$80.6 million, or 12.8 percent of all imports of the country. Iron and steel products were the largest group with a value of US$54.7 million followed by nonferrous metals US$6.5 million and industrial and other nonmetallic minerals accounting for the remainder.

COMMODITY REVIEW

METALS

Chromite.—In recent years the bulk of Iranian chromite has been obtained from two groups of mines in southeast Iran: Abdasht and adjacent mines of the Esfandageh Mining Co. and the Shahriar mine of the Faryab Mining Co. These two operating companies have practically the same ownership. Some ore has also been mined in recent years in the Forumad mine of the Iran Chromite Co. in northeast Iran, but it is doubted that Forumad was operating in 1963. These mines altogether exported 71,400 tons of chromite in the Iranian calendar year ending March 20, 1963. Iranian producers experienced difficulty in marketing their output during 1963 because of competition from other areas and because of sluggish market conditions, but toward the end of the year arrangements were made for sales to Japan.

Abdasht is close to Esfandageh village, and Shahriar is about 115 kilometers by air or 175 kilometers by road from Esfandageh. Ore from these mines is trucked to Bandar-e Abbas port. A $15 million U.S. loan is being used in developing and equipping this port. A modern road is being built, connecting Bandar-e Abbas with the city of Kerman. These improvements are expected eventually to reduce cost of moving the ore from mine to port.

Copper.—Output of copper did not exceed a few hundred tons of blister copper, which is usually refined in a small electrolytic refinery south of Tehran. The copper mines in the neighborhood of Anarak were probably the only ones in production during the year.

Iron Ore.—In an effort to find suitable domestic iron ore for a steel plant, Government organizations concerned with mineral exploration have examined a number of iron ore deposits by surface methods, diamond drilling, and adits.[4] In 1962 and 1963 these efforts were directed to Choghart and other iron deposits of the Bafq area. The Choghart deposit was explored by two adits, driven from the two ends of a hill in which the relatively massive deposit is situated, and a longitudinal drift along the axis of the deposit to connect the two adits and provide access for systematic sampling. Although the deposit is high-grade, phosphorus is present, and the purpose of the sampling is to ascertain the extent and distribution of the phosphorus within the deposit. Information on the results of the activities is not available.

Iron and Steel.—The Government remained committed to a long-sought project for establishing an integrated iron and steel industry based on Iranian raw materials. This project was actually started in 1936, but its implementation by German firms was interrupted by World War II. It has been pursued again since the early 1950's with assistance from a number of engineering firms and consultants which either prepared reports and proposals for a steel mill or evaluated the proposals. Problems involving raw materials and methods of financing the relatively large expenditures required have been principal reasons for the delay in implementation. The Government in 1963 reportedly intended to seek aid from the French Institut de Recherche de la Sidérurgie with respect to some of the raw material problems

[4] Bureau of Mines. Mineral Trade Notes. V. 57, No. 2, August 1963.

Digitized by Google

and the economic feasibility of a steel plant in Iran.

During the year a preliminary agreement was concluded between an American concern and a consortium of local engineering consultants for erection of a steel-rolling mill near Ahwaz. A local private bank and a number of Iranian capitalists were expected to participate. Necessary ingots for the rolling mill would be imported.

Steel requirements of the country were met by imports. In the Iranian calendar year ending March 20, 1962, the latest year for which official trade statistics have been published, bars, rods, and sections used in the building industry were the most important steel category with imports of 147,757 tons followed by flat products imports of 57,254 tons. Among the flat products, galvanized sheets are used extensively for roofing. Preliminary figures for the first 9 months of 1963 give steel imports of 251,407 tons values at US$45,849,000.

Lead-Zinc.—It is not known which of the many mines that in the past have produced lead-zinc ores were in operation during 1963. The bulk of the lead-zinc ore is exported, but some lead ore is smelted locally.

As a result of diamond drilling in three lead-zinc mines, carried out under a technical assistance program of the U.S. Agency for International Development, the probable reserve in these mines is estimated to have been increased by 10.5 million tons of ore with 21 percent zinc and 6 percent lead content. The three mines were Angouran (west of Zenjan with 4.25 million tons of new reserves), Koushk (near Bafq with 5.0 million tons), and Shahkuh (southwest of Esfahan with 1.25 million tons). Angouran and Koushk are owned by Iran Industrial & Mining Co. (Simiran) which reportedly in 1963 was negotiating an investment agreement with a British company to further explore and develop the deposit. The investment by the British company was to increase in stages depending on results of detailed work to be carried out. An American firm showed interest in the Shahkuh mine of Bama company.

NONMETALS

Besides building raw materials, only barite, salt, and sulfur were produced in commercial quantities for local consumption. Barite was consumed mainly by the oil industry. The bulk of the salt was produced for human consumption, although a small tonnage was used in manufacturing hydrochloric acid.

At the beginning of the year, there were eight cement plants in Iran with a total installed annual capacity of 800,000 to 850,000 tons, of which all but one were in operation. The majority of the plants are privately owned. The Lowshan plant was built in 1956 to supply cement to the Sefid Rud Dam and closed after the dam was completed in 1962; however, the plant may have been reopened during the year.

MINERAL FUELS

Petroleum.—*Exploration.*—During the year three geological survey parties were active in mapping structures and examining stratigraphic sections in Fars Province as well as in the northwest region of the Consortium Agreement area, in mapping of structures in Khuzistan, and in making a detailed study of the lithofacies of the Khami limestone. Three seismic reflection parties were devoted mainly to recon-

Digitized by Google

naissance of the alluvial plains of Khuzistan and more detailed structural delineation survey over certain known structures.[5]

There were 12 drilling rigs in operation in the Consortium Agreement area at the beginning of the year, of which 3 were for exploration, 8 for development, and 1 for workover. Because of greater efficiency in drilling and improved results, the number of rigs was reduced to 11 rigs at the end of the year, of which 4 were on exploration. Altogether, 45 new well completions and workovers were made, excluding 3 suspended and 2 abandoned new wells. Of these, 7 were for exploration, 26 were for development, and 12 were for workovers. A total of 321,195 feet (97,925 meters) of hole was drilled, 77,086 feet (23,502 meters) for exploration, 239,904 feet (73,141 meters) for development, and 4,205 feet (1,282 meters) for workovers. Drilling in 1963 added some 418,000 barrels per day to the production potential.

Exploration drilling in the Consortium area resulted in the establishment of Bibi Hakimeh (30 kilometers southwest of Gachsaran) as a major Asmari oilfield of high productivity, and discovery of a new field at Karanj northeast of Agha Jari. Bibi Hakimeh 3 and 5 were completed as prolific Asmari producers, while Bibi Hakimeh 4, an 11-mile outstep well, confirmed the continuation of a high structure southeast of the discovery well. The Karanj field is of moderate size compared with Agha Jari, but a very thick oil column was indicated. By proving a considerable extension of the Ahwaz field, development drilling added substantially to the reserves of the field. Drilling on Kharg island gave disappointing results. Mansuri, Khalafabad, Bushgan, and Gulkhari were classed as minor discoveries.

The NIOC was active in the Alborz area, in Gorgan, and in Emam Hassan 200 kilometers west of Kermanshah. Alborz No. 13 and Emam Hassan No. 1 were drilling as of November 1963 at 3,041 feet (927 meters) and 8,702 feet (2,650 meters), respectively. In Gorgan, Gorgan No. 3A was reported drilling at 7,082 feet (2,160 meters) in August.

IPAC completed an additional three wells in its Darius offshore field. As of November 1963, the company was reported drilling Darius 6 at 4,206 feet (1,282 meters) and Cyrus 5 at 5,686 feet (1,733 meters). SIRIP completed a seventh producing well at the end of 1963.

Production.—Crude production by the Consortium and other producers increased by 11.7 percent in 1963. The Consortium, still the dominant producer, set a new record of 1,444,000 barrels per day, a 10.9-percent increase from production in 1962. Consortium output was obtained from 8 fields with 117 producing wells distributed as follows at yearend: Agha Jari 38, Gachsaran 12, Ahwaz 7, the central fields (Masjed-e Soleyman, Lali, Haft Gel, and Naft Safid) 59, and Pazanum where production commenced toward the end of the year at 12,000 barrels per day. Agha Jari continued as the leading producing field with an average of 785,000 barrels per day (771,000 in 1962), followed by Gachsaran averaging 358,000 (287,000 in 1962). In the latter field, production unit No. 3 with 200,000-barrel-per-day capacity was commissioned during the year. Installation of permanent production facilities led to a substantial increase from the Ahwaz field to 97,000 barrels per day from 33,000 in 1962. The central fields

[5] Iranian Oil Operating Companies, 1963 Annual Review. Tehran, 1964, 44 pp.

Digitized by Google

maintained their production level at 204,000 barrels per day (211,000 in 1962).

Production of Gachsaran is scheduled to be increased further to 530,000 barrels per day. Laying of a second submarine pipeline was necessary to attain this objective. The pipeline parallels the submarine portion of the Gachsaran-Ganaveh-Kharg 26/28/30 inch pipeline which was built in 1960 and designed to move 330,000 barrels per day of crude by gravity. Capacity of the terrestrial part of this line has been increased by installations of pumping equipment which can be fully utilized when the second submarine line is completed.

With seven producing wells and completion of pipeline and shore terminal facilities, Société Iran-Italienne des Pétroles (SIRIP)[6] increased its crude output by 238 percent. These facilities include a 23-mile 16-inch underwater pipeline from the Bahrgansar field to a land terminal consisting of five storage tanks having a total capacity of 62,000 tons, a crude desalting unit, and a 6-mile 18-inch pipeline to a deepwater tanker facility.

Iranian Pan American Oil Co. (IPAC)[7] was not producing crude commercially pending completion of loading facilities on the Kharg Island expected in late 1964. IPAC plans to produce initially at the rate of 50,000 barrels per day from the Darius field, and production is to be gradually increased to 100,000 barrels per day.

[1] Test production.

Refining.—Refinery throughput at Abadan refinery of 132,306,000 barrels was 1.1 percent more than in 1962 (130,855,000), and averaged 382,481 barrels per day (358,507 in 1962). Of the total throughput 111,034,000 was for the account of the Trading Companies; that is, for export as products, and 21,272,000 for the account of the NIOC, the products being entirely for internal consumption. Quantities of Ahwaz crude processed at the refinery rose to 110,000 barrels per day by yearend (32,172, in 1962).

Shipment of refinery products from Abadan increased 3 percent from shipments in 1962: 122,348,500 barrels in 1963 and 118,662,200 in 1962. In 1963, 102,651,900 barrels were exported and 19,697,000

[6] For ownership of SIRIP and IPAC and details on their concession areas see Bureau of Mines Information Circular 8203, 1963.
[7] Work cited in footnote 6.

Digitized by Google

were delivered to the NIOC. Total shipments in 1963 consisted of the following, in barrels: Liquified petroleum gas 100,737; aviation gasoline 4,951,103; motor gasoline 16,944,562; aviation turbine fuel 7,008,183; kerosine 14,199,199; special solvent 1,257,663; vaporising oil 1,701,330; gas oil 17,299,442; diesel oil 4,149,634; fuel oil 53,565,102; lubricating oil 156,588; and bitumen 1,014,972. NIOC produced a total of 3,022,173 barrels from the Kermanshah refinery and the Naft-e Shah topping plant (2,937,739 in 1962) and obtained an additional 938,182 barrels of gas oil from processing of Alborz crude.

TABLE 6.—Output of refined products

[1] Excludes products from Masjed-e Soleyman and Naft-e Shah topping plants which may have been shipped without further refining.

Three large kerosine treating units, each with a capacity of 13,500 barrels per day using copper chloride as a sweetening catalyst, were commissioned in Abadan. These replaced the older acid refining process in the production of high-grade illuminating kerosine. By installation of side reflux systems and increased heater capacity in three of the four major crude distillation units of the Abadan refinery, performance of these units was increased and provided for maximum gas oil recovery at full throughputs of up to 110,000 barrels per day.

On May 30, the NIOC as an authorized agent of the Iranian Government signed a contract with a French and German consortium for the financing and construction of a refinery in Tehran and a 20-inch crude pipeline from Alborz and a 20-inch gas pipeline from Sarajeh to Tehran. The German participants, consisting of Phoenix Rheinrohr International, Stahlunion Export, and Mannesman Export would finance and construct a 4-million-ton-per-year refinery at a cost of $80 million to utilize Alborz crude. The French (Société Entrepose) would finance and construct the two pipelines. These contracts had not been implemented at yearend. The decision of NIOC to construct a second products pipeline from Ahvaz to Tehran has caused postponement of its plan for the Sarajeh-Tehran gas pipeline.

Digitized by Google

Domestic Sales.—According to NIOC, sales of petroleum products amounted to 29,062,488 barrels of refined products. Of this total, kerosine represented 7.91 million, fuel oil 7.74 million, gas oil 7.28 million, and gasoline 4.42 million barrels. The remaining 1.71 million barrels comprised all other products. The 3.2-percent increase in consumption continued the downward trend in the gains of earlier years: 5.7 percent per year in 1962 and 9.4 percent in 1961. About 86 percent of product consumption was supplied by the Abadan refinery and the Consortium's topping plants at Masjid-i-Soleyman.

Sales are carried out by 58 branches, 117 filling stations, 85 agencies, and 2,500 dealerships.[8] The distribution organization of the NIOC is entrusted with the procurement, transportation, and distribution of petroleum products and derivatives as well as of natural and liquefied gas.

The role of pipeline in transportation of products has increased, and over 50 percent of products are transported by pipeline. The 105-kilometer Qazvin-Rasht extension of the Tehran-Qazvin-Rasht pipeline was under construction.

Natural Gas.—Of the associated natural gas produced in 1963, which was 12.5 percent more than in 1962, only 11 percent was fully utilized. The Marvdasht fertilizer plant near Shiraz, the first project to utilize natural gas outside of the oilfields, was formally opened in October. The plant, designed to produce urea and ammonium nitrate equivalent to 30,000 tons of nitrogen, receives treated gas from a plant in Gachsaran with 20-million-cubic-feet-per-day capacity through a 265-kilometer 10-inch pipeline. A cement plant and a sugar refinery will also use the gas. Further utilization of natural gas for production of petrochemical was under active study by the Plan Organization, the governmental agency which is responsible for administration of Iran's economic development programs.

The Mineral Industry of Iraq

By F. L. Klinger [1]

PETROLEUM is the most important mineral product of Iraq. Crude petroleum produced in 1963 constituted 17 percent of Middle East production and 4 percent of world output, and Iraq ranked fifth in world petroleum exports. Iraq also produced petroleum products, salt, and construction materials for domestic consumption. Gypsum and natural bitumen were formerly mined, and deposits of iron and phosphate rock were being investigated at the end of the year.

In 1962, products of the petroleum industry were valued at an estimated 258 million dinars (US$722 million).[2] This was 97 percent of the value of all mineral products and more than 50 percent of the gross national product. In the same year, the petroleum industry (excluding marketing and distribution) employed an estimated 15,500 persons, 85 percent of all mineral industry workers and 23 percent of total estimated industrial labor.

Petroleum revenue provides most of Iraqi foreign exchange earnings and more than half of all government revenues. Under a 1952 agreement with the Iraq Petroleum Co.[3] (IPC), the government receives 50 percent of all company profits before foreign taxes. This revenue amounted to US$266 million in 1962 and a record US$308 million in 1963. IPC also supplies crude petroleum at cost to government refineries which annually produce about 15 million barrels of petroleum products.

Outstanding developments in 1963 were an alltime record in petroleum production, the settlement of a dispute between the government and IPC on cargo and port taxes to be levied on tankers loading petroleum at the port of Basra, and the exemption of shipping companies from income taxes on profits realized from Basra oil liftings. The last two issues had been largely responsible for the steady decline in Basra oil exports since 1959, and their settlement contributed to the significant increase in national petroleum output during 1963.

Law No. 80, passed in December 1961, continued to be the most important factor in relationships between the government and the petroleum companies. Under this law, 99.5 percent of the petroleum concessions held by IPC companies were withdrawn from company control, including those areas with proven but undeveloped petroleum reserves. The IPC has not accepted the legality of this action, but the law was reiterated by the government early in 1964 when it estab-

Digitized by Google

lished the Iraqi National Oil Co. This company will be authorized to engage in all phases of the petroleum industry including petrochemicals, and to explore all areas for oil with the exception of those areas allocated to the IPC companies under Law 80.

Of potential significance to the mineral industry is the new 550-kilometer standard-gage railway under construction between Baghdad and Basra. Track laying was completed by early 1964, and the last of 1,600 freight cars ordered from Poland were expected to arrive during this year. The railway is to be operational in the spring of 1965.

PRODUCTION

Petroleum production in 1963 was 15 percent greater than in 1962. This rise resulted from production increases of 8.5 percent (26 million barrels) in the Kirkuk fields, and 44 percent (28 million barrels) in the Zubair-Rumaila fields of Basrah Petroleum Co. There was no significant change in the output of other minerals.

In 1962 the mineral production of Iraq was valued at an estimated 266 million dinars (US$745 million). Of this total, petroleum accounted for 91 percent, refinery products, 6 percent, and other materials, 3 percent.

TRADE

Metal and mineral exports in 1962 were valued at US$630 million, or 91 percent of all exports. Of this value, petroleum made up 99.5 percent and cement, 0.3 percent. Petroleum exports in 1963 increased 15 percent over those of 1962 and were equivalent to nearly 96 percent of petroleum output. Seventy-five percent of the exports were by pipeline to the Mediterranean and the remainder by tanker from Basra. As in previous years, Western Europe was the largest recipient of Iraqi petroleum.

Digitized by Google

Iraq must import all of its metals and most requirements of industrial minerals. Metal and mineral imports in 1962 were valued at US$35.6 million, or approximately 10 percent of all imports. Iron and steel were the most important items, valued at US$30 million (8 percent of all imports), followed by nonferrous metals (0.8 percent), nonmetallic minerals (0.5 percent), and mineral fuels (0.2 percent). Metal and mineral imports in 1962 were not significantly different from 1961 levels, except for copper imports which nearly doubled.

Several changes in Iraqi trade policy occurred during 1963. Trade restrictions were lifted from many commodities as well as from several countries including Lebanon, United Arab Republic, Japan, France, Italy, and the United Kingdom, and a swing in trade from Communist countries towards the West was reported. Little or no change was reported in Iraqi tariffs. Iraq has a single-column tariff but gives preference to commodities imported from Arab states. Raw materials needed for industry are duty-free, but import taxes of up to 6 percent of c.i.f. value are imposed on several items, including rolled steel products; higher taxes are levied on imports of mineral commodities which can be produced within the country.

COMMODITY REVIEW

METALS

Iron and Steel.—No decision had been reached on the proposed Baghdad steel mill by the end of 1963. Bids on feasibility studies, design, and supervision of construction of the mill still were being received in December. Originally a Soviet-sponsored project, the mill was to have an annual capacity of 70,00 tons of iron and steel products, using imported scrap as raw material. Early in the year, a large iron deposit reportedly was discovered in the western desert by Soviet prospecting teams. The deposit originally was estimated to contain 300 million tons of ore with an average iron content of 60 percent, but more recent reports indicate that these figures are too high.

NONMETALS

Cement.—Cement production in Iraq in 1963 was 64 percent of total rated capacity, slightly below the level of 1962. In 1962, about 13 percent of production was exported, with the remainder used mostly for dam and bridge construction. An estimated 40,000 tons was used in the manufacture of prestressed concrete and asbestos-cement products.

Production facilities include six plants, two of which are government-owned, with a total rated capacity of 1,400,000 tons per year. Productive capacity is well in excess of demand, because of overbuilding before 1958. The industry produces sulfate-resistant cement as well as portland (types II and IV).

A drop in cement consumption may have occurred in 1963 because the large Derbendi Khan Dam project was nearing completion. Increased exports to Kuwait were likely, however, and if a cement plant is not built in Kuwait it is possible that Iraq will establish a plant west of Basra to supply Kuwaiti requirements.

Ceramic Materials.—In 1963, bids were invited for feasibility studies, design, and supervision of construction of a ceramics plant at Ramadi. As presently conceived, this plant would annually produce housewares (3,000 tons), sanitary ware (2,500 tons), wall tile (3,000 tons), and undetermined quantities of firebrick and drainpipe.

Construction of a glass plant also is planned at Ramadi. The plant evidently will be built under a Soviet aid agreement and much of the equipment has already arrived. The plant is to have a capacity of

Digitized by Google

22,000 tons of glass per year and will utilize local resources of sand and dolomite.

MINERAL FUELS

Petroleum and Natural Gas.—Petroleum production averaged 1.15 million barrels per day in 1963. The largest producer was IPC, which at the beginning of 1963 had 87 wells producing nearly 800,000 barrels per day from the Kirkuk fields of northern Iraq. Basrah Petroleum Company had 63 wells producing 180,000 barrels per day from the Zubair-Rumaila fields in the southeast; of the remaining production, 26,000 barrels per day were produced from 16 wells of the Mosul Petroleum Company and an estimated 5,000 barrels per day came from government-owned wells in the Naftkhaneh field northeast of Baghdad. Total reserves in 1963 were estimated [4] at more than 24,000 million barrels. Iraq also has natural gas resources estimated at 22.5 million million cubic feet.[5]

Principal developments in productive capacity during the last 2 years were in transportation and processing facilities. BPC's new deepwater loading terminal at Khor al-Amaya was commissioned in April 1962 and doubled the annual loading capacity at the port of Basra to 22 million tons. Since then, BPC also has completed construction of a 30-inch, 65-mile pipeline from the oilfields to the Fao tank farm; three new degassing and pump stations in the Rumaila field; and 57 miles of 16-inch pipelines. In 1962, IPC increased capacity of its processing plant at Kirkuk to 250,000 barrels per day.

The IPC companies did no exploration drilling in 1961–63. In 1962, IPC and MPC completed 20,000 feet of development drilling which brought in four producing wells and increased production by 3,000 barrels per day. In 1963, IPC drilled seven development wells in the Kirkuk field, and the government used a Soviet rig to drill one well at Naftkhaneh.

During the first 6 months of 1963, refinery output appeared to be slightly below the level of 17 million barrels reached in 1962. The Qaiyara bitumen refinery, idle since 1958, was reactivated late in 1963 and was scheduled to produce 50,000 tons per year of bitumen along with heavy and light fuel oils. A 12-inch, 130-kilometer pipeline was completed during the summer from Khanaqin to the al-Daura refinery near Baghdad and reportedly was supplying Naftkhaneh crude to the plant in late 1963.

In 1963 the government asked for bids on design and construction of a sulfur recovery plant at Kirkuk, and in early 1964 contracted with the Italian firm of Techint for evaluation of bids and supervision of construction. Award of a construction contract was expected by mid-1964. It is believed that the proposed plant will use natural gas to produce gasoline, LP gases, and 300 to 350 tons per day of sulfur. The plant also will supply cleaned gas for commercial use. In connection with this project, a contract was made early in 1964

with a French firm for consulting services and for designing a 200-mile natural gas pipeline from Kirkuk to Baghdad.

In other 1963 developments, the government asked for bids on construction of a 630,000-barrel petroleum products storage depot at Zaafaraniya in Baghdad. Bids submitted for feasibility and marketing surveys for a petrochemicals plant and a fertilizer (ammonium sulfate) plant at Basra were being considered. A French firm, Petro-Chimie, S.A., was appointed to study the developments of production facilities for fertilizers based on natural and refinery gas in Iraq.

The dispute between Iran and Iraq over sovereignty of an offshore area at the head of the Persian Gulf remained unresolved at yearend.

The Mineral Industry of Israel

By F. L. Klinger[1]

PRODUCTION of Israel's small but relatively diversified metal and mineral industry increased during 1963. Preliminary data suggest that the total value of production increased 10 percent over that of 1962, when output was valued at an estimated US$82 million or 4 percent of the gross national product. About 55 percent of the 1962 value (US$46 million) originated from domestic resources which include potash, copper, phosphate, bromine, oil and gas, and various construction materials. The remainder was value added by the diamond-polishing, petroleum-refining, and steel industries, which are largely dependent upon imports. The diamond-polishing industry ranks first in foreign exchange earnings, producing a net added value of US$15 million in 1962 or four times the value of either potash or copper exports. Israel's diamond-polishing industry is second only to Belgium and accounts for about 25 percent of world exports. In addition, the potash, bromine, and phosphate resources have fostered a chemicals industry which manufactures fertilizers and other chemical products at the rate of 300,000 metric tons per year. An estimated 15,200 persons, or about 2 percent of the national labor force, were employed in these industries in 1963—56 percent in diamond polishing, petroleum refining, and steelmaking; 35 percent in domestic mineral production; and 9 percent in the chemicals industry.

GOVERNMENT POLICIES AND PROGRAMS

Except for the steelworks at Acre, which is owned by the General Federation of Jewish Labor (Histadrut), and diamond polishing, the mineral industry is principally owned and operated by the Israeli Government. Mineral exploration and development are also carried out or controlled by government agencies, principally through Israel Mining Industries, Ltd. (IMI). A continuing program of applied research has developed new and cheaper processes for the manufacture of phosphoric acid, carbon steel, and tetrabromoethane (TBE). TBE, produced from Dead Sea brines, has been successfully applied to minerals beneficiation on an industrial scale. These processes have created international interest and are being used or tested in the United States, Europe, and Japan.

Improvements underway in basic transportation included construction of a new port facility at Ashdod and a 30-kilometer railway spur from Beersheba to Dimona.

PRODUCTION

The general increase in production of Israel's mineral industry in 1963 was marked by substantial gains in several key commodities. As compared with 1962, production of phosphate increased by 42 percent, cement-copper by 30 percent, potash by 24 percent, and petroleum products by about 15 percent. Output of bromine and bromine compounds increased by nearly two-thirds although the aggregate tonnage was only about 40 percent of the quantity produced in 1961. The demand for construction materials remained strong and cement production increased by 100,000 metric tons.

The aggregate value of mineral and metal production in 1963 was estimated to be US$90 million. Of this total, construction materials were estimated to have accounted for 33 percent, followed by mineral fuels (20 percent); polished diamonds (16 percent); metals (13 percent); potash, phosphate and bromine (11 percent); and other materials (7 percent).

TRADE

In 1963, exports of diamond, potash, copper, raw phosphate, and bromine products were substantially greater than in 1962 and showed an aggregate increase in value of 24 percent. Available export data follows: Cement copper 10,297 tons; bromine and bromine compounds

Digitized by Google

2,941 tons; clay 5,434 tons; cement 99,000 tons; polished diamond (gross exports) 1,155,000 carats; phosphate rock 124,888 tons; and potash 164,231 tons.

Exports of metals and minerals in 1962 were valued at an estimated US$109 million, or 38 percent of all exports. Polished diamonds were the most important commodity, accounting for 32 percent of the value of all exports, followed by nonmetallic minerals (3 percent), metals (2 percent), and mineral fuels (1 percent).

TABLE 3.—Imports of metals and minerals [1]—Continued

(Metric tons unless otherwise specified)

Commodity		1961	1962
Mineral fuels:			
Coal		17,892	20,445
Peat briquets		225	483
Coke, including semicoke		27,545	26,009
Coal tar and derivatives		(2)	3,364
Petroleum:			
Crude	thousand 42-gallon barrels	10,760	15,208
Refinery products:			
Gasoline	do	76	70
Kerosine	do		12
Diesel oil	do		32
Residual fuel oil	do	4,097	2,592
Lubricants, including grease	do	97	119
Waxes	do	14	16
Other	do	17	21
Total refined products	do	4,301	2,862

[1] Countries of origin not available.
[2] Estimated from official import values.
[3] Data not available.

In 1962, imports of metals and minerals were valued at US$185 million or 29 percent of all imports. Rough diamonds were valued at nearly 12 percent of all imports, followed by mineral fuels (7 percent), iron and steel (7 percent), other metals (2 percent), and nonmetallic minerals (1 percent). Increased allocations from the Diamond Trading Co. increased volume of diamond imports by 31 percent as compared with 1961. Expanded capacity and production at the Haifa refinery was responsible for a 41-percent increase in imports of crude petroleum as well as a 33-percent decrease in imports of refinery products. Imports of rolled iron and steel products increased by 18 percent, and substantial but less significant increases were recorded in aluminum, cement, and sulfur. In 1963, the value of all Israeli imports rose by US$46 million, or 7 percent, over that of 1962; more than half of this total was accounted for by diamond imports.

Although countries of destination and origin are not shown in tables 2 and 3, Israel's foreign trade is conducted principally with the United States and members of the European Economic Community (EEC) and European Free Trade Association (EFTA) organizations. These countries supply about 90 percent of all Israeli imports and receive about 80 percent of all exports.

COMMODITY REVIEW

METALS

Copper.—Cement-copper production in 1963 increased by approximately 30 percent over that of 1962. All production came from the government-owned mine and plant at Timna, 25 kilometers north of Eilat. The proved ore reserve at Timna is estimated to be 15 million tons containing 1.89 percent copper, although mine-run material appears to contain between 1.25 and 1.5 percent copper. The main ore

Digitized by Google

mineral is chrysocola. Ore production in 1963 totaled about 500,000 tons from open pit and underground mines; this has been the average for the last 5 years.

With open pit reserves diminishing, production from the underground mine increased to 20 percent of total production in 1962–63. Underground development, underway since 1959, includes more than 6 kilometers of tunnels. An expansion plan to produce 15,000 tons of copper annually, mostly from underground ore, was deferred temporarily in October, pending further cost studies of underground mining.

Copper was extracted by a sulfuric acid leach process and subsequently cemented. The plant treated about 1,500 tons of ore daily, producing about 25 tons of cement copper with a metal content of 75 percent. Sulfuric acid (90 tons daily) was made at the site, using a vanadium catalyst contact converter and imported sulfur.

Iron and Steel.—No primary iron has been produced on a commercial scale from domestic deposits. Beneficiation research and mine development presumably continued on the Har Ramin hematite deposits of Upper Galilee. These deposits are estimated to contain 40 million tons of material having an iron content of 26 to 28 percent. If the iron content can be raised to 42 percent, the material may be usable at Acre.

The Acre steelworks had an estimated capacity of 100,000 tons of steel products made from ingots, scrap, and iron ore. The plant was in operation in 1963, but production was not reported. In mid-1963, the Acre works reportedly was stopping imports of scrap and switching to the purchase of ingots abroad.

NONMETALS

Cement.—In spite of a 40-percent decline in exports caused by reductions in sales to Turkey, production of cement increased by 11 percent. The increase was mainly due to the demand created by construction projects at Ashdod Port and the Dead Sea Works. The government-controlled Nesher Cement Co. announced operation of a second kiln at its Ramleh works in November, and reported a third kiln under construction. Operation of the new kiln, which has a capacity of 210,000 tons annually, raised capacity of this plant to 370,000 tons and increased the capacity of the Israeli cement industry to an estimated 1.4 million tons. Two cement products plants, one for ready-mixed concrete and the other for cement blocks, were opened in Beersheba during 1963.

Diamond.—Israel's diamond trade increased substantially in 1963. As compared with 1962, net imports of gem diamonds increased by 37 percent and net exports by 25 percent. However, owing to a higher proportion of returned stones, the net earnings were about 20 percent less than in 1962. Prospects for the industry in 1964 were uncertain, owing to a serious cut expected in allocations of rough diamonds from the Diamond Trading Co. and an expected 9-percent increase in labor costs.

Flint Clay.—In 1963 a new plant for the calcining and magnetic beneficiation of flint clay was under construction at Makhtesh Ramon in the Negev. Earlier in the year, a partnership was formed between

Digitized by Google

the government-owned Ceramics & Fine Sands Co. and an Italian firm. A total investment of US$3.3 million was anticipated.

Phosphates.—Phosphate deposits of Oron, mined and processed by the government-owned Chemicals Phosphate, Ltd., continued to supply practically all of the country's output. In 1963 production rose 40 percent as the country's new calcining plant went into operation. This plant is expected to make possible an annual production of 400,000 tons of phosphate containing 35 to 38 percent phosphorus pentoxide (P_2O_5) from open pit ore containing 24 percent P_2O_5. Also completed during 1963 was a pipeline from the Zohar gasfield to Oron, which will supply fuel for plant operations. In January 1964, the company began constructing a processing plant for phosphates and limestone at Arad, 60 kilometers north of Oron. The plant is the first unit of the company's planned chemical complex at this site.

The same company discovered a new phosphate field at Zefa Ef'eh, north of Oron and only 5 kilometers south of the S'dom-Dimona highway.

In late 1963 Israel American Phosphates, Ltd., a private concern, was preparing to begin open pit mining at the Ein Yahav deposits, 35 kilometers southeast of Oron. Tenders were issued for overburden removal, and heavy equipment was on order. This company is also exploring deposits to the south and west, at Har Hameishar and Hor Hahar.

At the end of 1963, phosphate deposits were known at six localities, distributed over an area of about 5,000 square kilometers in the central and southern Negev. Minimum total reserves appeared to be about 80 million tons.

Potash and Bromine.—Potash production from the Dead Sea Works at S'dom was about 15 percent greater than in 1962. Increased output was due to favorable weather and to new evaporation areas made available by the large expansion project which was still underway at the end of the year.

The expansion project will cost US$70 million when completed; it will add 100 square kilometers to the original evaporation area by diking off part of the Dead Sea and will increase annual production capacity to 600,000 tons. Construction was scheduled for completion in 1965. Two-thirds of the planned evaporation area was expected to be available in 1964 as two of three new evaporation basins were nearly

TABLE 4.—Phosphate deposits and reserves in 1963

Digitized by Google

completed. The government plans to invest an additional US$16.6 million to increase production capacity to 900,000 tons by 1972.

In 1963 construction continued on a new processing plant which was to be completed in April 1964. The plant will employ a hot-leach process to improve potash recovery and quality, and will use natural gas piped from the Zohar gasfield.

Residual brines from potash production contain bromine and chlorides of sodium and magnesium, but in 1963 only bromine and sodium chloride were recovered. After successful production of magnesium oxide from magnesium chloride on a pilot plant scale, plans to build a refractory brick plant were announced in early 1963 but were later deferred because of uncertain market conditions.

Elemental bromine is produced only at the Dead Sea Works plant at S'dom, which has an annual capacity of 10,000 tons. Output fell sharply in 1962 owing to market restrictions in the EEC countries. In 1963 production increased by about 60 percent but was running well below total capacity. In January, a new bromine plant with an annual capacity of 2,000 tons was opened in Beersheba.

MINERAL FUELS

Crude Petroleum.—Development of the new Kokhav field north of Heletz-Brur led to a 10-percent increase in Israeli petroleum production. Domestic production now supplies about 10 percent of demand.

In 1963 production from the Heletz-Brur field averaged about 2,660 barrels per day from 27 wells; by midyear this was augmented by an estimated 600 barrels per day from the three wells at Kokhav. Petroleum was found in four additional wells at Kokhav later in 1963 but the added production is unknown. One of these wells (Kokhav 10) was expected to yield over 1,000 barrels daily, but a heavy flow of salt water was later encountered. Development drilling at Kokhav during the year was estimated to total 17,000 meters and at least 10 wells were completed. Elsewhere in the country, drilling was reported at four locations: Two in the Negev, one south of Heletz, and one south of Haifa. Total reserves in all fields were estimated at 27 million barrels, compared with 15 million barrels at the end of 1962.

In mid-1963 the government approved new regulations for petroleum prospecting. The maximum area held by a single concessionaire in any one district was increased to 1 million acres. Concession fees also were increased, and the applicant is now required to submit details of financing as well as a program for exploration.

Refinery Products and Petrochemicals.—Output of the Haifa refinery during 1963 was reportedly 2.63 million tons of petroleum products. This indicates a 15-percent increase over that of 1962 and a 100-percent increase over 1959. Fuel oils accounted for most of the increase in production. A program of modernization and new construction which began in 1961 was continued during 1963. The capacity of the refinery was expected to increase to 3 million tons in 1964 and 4 million tons in 1965. The modernization program includes installation of a new catalytic cracking unit.

The first plant of the petrochemicals complex at Haifa started producing ethylene in December 1963. The plant's capacity is 15,000 tons

Digitized by Google

per year. A carbon-black plant with an annual capacity of 20 million pounds was scheduled to begin production in January 1964 and a 6,000-ton polyethylene plant was scheduled for production in April.

Natural Gas.—Natural gas production increased at an unspecified rate during 1963 with completion of a new pipeline from the Zohar fields to industrial plants at Dimona and Oron and increased consumption at S'dom. At the beginning of the year Zohar gas was being supplied to the Dead Sea Works at the rate of 350 million cubic feet per year, an increase of 30 percent as compared with 1962. Gas from the new Hakanaim field, just north of Zohar, was connected with the Zohar distribution system late in 1962 and had produced 218 million cubic feet by February 1, 1963.

Total gas reserves are unknown, but reserves in the Zohar field were estimated to total 53,000 million cubic feet in late 1961.

The Mineral Industry of the Hashemite Kingdom of Jordan

By L. Nahai [1]

PHOSPHATE ROCK has been Jordan's principal mineral product. Output in 1963 was slightly over 1 percent of world's total. The country will begin making a small contribution to the world potash supply when the present project for utilization of potash from the Dead Sea comes into production.

Although Jordan's mineral output is quite small, it is important to its national economy. Phosphate rock accounts for nearly 30 percent of the value of total exports. The Jordanian cement plant and petroleum refinery meet a part of domestic demands for these products. Most construction raw materials are generally available throughout the country.

The 1963 value of mineral output was JD4,835,000 [2] (US$13,538,000). This does not include the value added by the petroleum refinery to the crude oil which Jordan receives from Saudi Arabia through the pipeline of the Trans-Arabian Pipeline Co. (Tapline) which crosses Jordan. Value of mineral production was equal to 4.2 percent of the estimated 1962 gross national product and consisted essentially of phosphates (US$7,246,000) and cement (US$5,929,000). It is estimated that 2,500 persons were engaged in mines and quarries and in the plants processing these raw materials and imported crude oil.

PRODUCTION

The value of minerals (except petroleum refinery products) produced in Jordan in 1963 apparently declined by about JD166,000 (US$465,000) from the level attained in 1962, primarily as a result of a 67,000-ton decline in phosphate production but also because of declines in marble and salt output. The gain in cement output of about 50,000 tons partly compensated for these declines. Generally, over the 5-year period 1959–63, Jordanian mineral output has shown appreciable gains.

---

[1] Near East-South Asia specialist, Division of International Activities.

[2] The monetary unit of Jordan is the Jordanian dinar (JD). Conversion to U.S. currency has been made at the rate of JD1.00=US$2.80. The value of mineral production is a total of reported values for each of the nonfuel commodities listed in the production table except for gypsum, the value of which was estimated on the basis of the 1962 reported value of production.

[4] Estimate, based on reported 10-percent increase in refinery output.

TRADE

Except for salt and construction materials, most of Jordan's mineral and metal requirements must be provided by imports. Total value of these imports in 1962 was JD5,596,000 (US$15,669,000), or 12 percent of total imports. Principal imports and their equivalent values in dollars were as follows: Crude petroleum US$3,661,000; petroleum refinery products US$3,622,000; iron and steel US$6,283,000; nonferrous metals US$547,000; cement and clinker US$918,000; fertilizers US$358,000; and other nonmetallic minerals US$280,000.

In 1962 bars and rods constituted 55 percent of iron and steel imports followed by angles, shapes, and sections (13 percent), pipes and fittings (10 percent), and flat products (4 percent). Most of the steel is used in construction, but a small amount is used in fabrication of metal furniture and other products at the handicraft level.

Phosphates were Jordan's largest single export. The 1962 exports valued at JD1,456,152 (US$4,077,000) amounted to 29.5 percent of the country's total domestic exports.

COMMODITY REVIEW

METALS

Copper.—The government concluded an agreement with a West German firm to carry out detailed exploration and feasibility studies for the exploitation of copper deposits in Wadi Abu Khusheiba, about 100 kilometers north of Aqaba port. These deposits were discovered by the German Geological Mission which has been operating under a technical assistance agreement with Jordan since April 1961.

NONMETALS

Phosphate Rock.—Detailed investigations of the Hasa phosphate deposits, nearly 200 road kilometers north of Aqaba port, were carried out during the year by Ralph M. Parson Co. It is believed these deposits may contain more than 30 million tons of ore. A plant for beneficiating some of the phosphate produced at Al Roseifa mine, 15 kilometers by road northeast of Amman, also came into operation. The bulk of 1963 output was from this mine, but production was being shifted to the Al Hasa deposits which are closer to Aqaba port by about 160 kilometers.

To increase the export of phosphate, the port fees at Aqaba were reduced to 5.6 cents per ton from former duties which varied from 5.6

Digitized by Google

to 12.6 cents per ton depending on tonnage exported. Planned expansion of the Aqaba port through a JD1,350,000 (US$3,780,000) loan from West Germany will be significant to the phosphate trade. Buildings and pier facilities reportedly will be expanded so that the port may handle 1,500,000 tons of phosphate annually, the eventual target of phosphate production in Jordan.

MINERAL FUELS

Petroleum.—There was no petroleum exploration in Jordan during 1963, but the West German firm Gewerkschafe Elwerath Erdoeworke of Hanover sent representatives to Jordon to negotiate oil prospecting rights. The crude oil throughputs in the petroleum refinery at Zerka during 1961 and 1962 were the same as crude oil imports shown in table 3. The larger throughput in 1962 did not result from any additional equipment but by the more efficient operation of existing facilities.

The Mineral Industry of Kuwait

By F. L. Klinger[1]

KUWAIT was the leading petroleum-producing country of the Middle East in 1963. In recent years it has produced about 7 percent of the world's annual petroleum supply and has been second only to Venezuela in the volume of petroleum exports. In addition nearly one-fourth of the world's proved petroleum reserve is in Kuwait. The country has no other known mineral resources except for natural gas and a few construction materials.

The Kuwait economy is almost totally dependent on activities of the petroleum industry. Estimated value of production of petroleum and refinery products[2] was US$1,140 million in 1963 and was nearly equal to the value of the gross national product. Government revenue from petroleum, estimated at nearly US$500 million in 1963 (including income from the Kuwait-Saudi Arabian Neutral Zone), provided 94 percent of all government revenue and practically all foreign-exchange earnings.

The petroleum industry employs an estimated 5,000 persons, 6 percent of the country's labor force and has indirectly created a construction industry employing more than 20,000. Important new water supplies, cheap industrial fuel, a new commercial port facility, and increasing electric power also have resulted from petroleum exploration, development, and revenue. Kuwait's wage scale was reported to be the highest in the Middle East and the national income, on a per capita basis, was one of the highest in the world.

All petroleum production in Kuwait proper was from onshore fields of the Kuwait Oil Co. (KOC), owned equally by British Petroleum Co. (BP) and the Gulf Oil Corp. Offshore explorations were conducted by KOC and a subsidiary of the Royal Dutch Shell Group. In the Kuwait-Saudi Arabia Neutral Zone, Kuwait's onshore concession is leased to the American Independent Oil Co. and offshore areas (beyond the 6-mile limit) are leased to the Japanese-owned Arabian Oil Co. Essentially all of Kuwait's revenue from petroleum has been obtained from KOC and companies operating in the Kuwait-Saudi Arabia Neutral Zone. Under the KOC agreement, the government received 50 percent of the difference between production costs and the posted price of crude oil produced.

The most notable recent development in Kuwait petroleum affairs took place in May 1962, when the Kuwait Oil Co. relinquished half of

---

[1] Foreign mineral specialist, Division of International Activities.
[2] Estimated on the basis of posted crude prices at Mina al-Ahmadi and posted refinery product prices at Ras Tanura.

Digitized by Google

its original concession area to the government and agreed to release an additional 1,000 square kilometers of offshore area by 1967. Exploitation rights in the relinquished area were subsequently assigned to the government-controlled Kuwait National Petroleum Co. (KNPC). KNPC, which was established in 1961, also handles the distribution of petroleum products in Kuwait, receiving its supplies from KOC at cost. In 1963 KNPC acquired control of 51 percent of the aviation fueling concession which was formerly owned by the BP. The remaining 49 percent of stock was retained by BP.

Other developments in 1963 included a 5-percent increase in crude oil production, a 30-percent increase in refinery capacity, and suspension of onshore and offshore exploration drilling in the northern and western part of the country owing to unsettled boundary disputes between Iraq, Iran, and Kuwait. There was also a possibility that definition of the southern boundary of Kuwait would transfer some of KOC's concession area to the Neutral Zone, notably the Umm Gudair field.

PRODUCTION

Kuwait's petroleum production in 1963 was estimated at 28 percent of Middle East production and 7 percent of total world output. The average daily production of 1,932,800 barrels was an increase of nearly 100,000 barrels per day or 5 percent more than in 1962. Production of construction materials was not reported specifically but accounted for an inconsequential share of the total value of mineral output.

TABLE 1.—Production of petroleum and petroleum products

(Thousand 42-gallon barrels)

	1959	1960	1961	1962	1963

Total output refined products, including refinery fuel and loss	52,016	64,943	62,433	70,881	74,069

TRADE

About 18 percent of world petroleum exports originated in Kuwait. Kuwait also has been an import center for goods destined for neighboring areas. The country has a liberal trade policy, and although preference is given to imports from other Arab States, there are no bilateral trade agreements and few export or import controls. Almost all imported commodities are either exempt from duty or are taxed at 4 percent ad valorem. In 1963 Kuwait became a full member of the General Agreement on Tariffs and Trade.

Digitized by Google

The volume of petroleum and refined products exported in 1963 increased by 5 percent over that of 1962. These commodities were valued at more than US$1,000 million, with crude oil accounting for about 90 percent of the value of all exports and refinery products for 8 percent. Seventy-five percent of the crude and 65 percent of the refined products were destined for western Europe and Japan. All exports were by tanker.

Import statistics for 1963 are not available. In 1962 imports of metal and mineral products were valued at an estimated US$23 million or 8 percent of all imports. Cement was the largest single item, accounting for more than half the tonnage of all imports and possibly 4 percent of the total value, followed by iron and steel products (estimated at 4 percent of total value) and petroleum products (0.2 percent).

TABLE 2.—Exports of mineral fuels

(Thousand 42-gallon barrels)

	1962	1963	Principal destinations, 1963
Crude petroleum	599,630	629,158	United Kingdom 163,595; Japan 97,307; Italy 94,798; France 56,786; Netherlands 44,493; United States 35,576; Australia 24,622; Malaya and Singapore 21,442; Aden 18,093; Belgium 15,114; West Germany 11,220; Brazil 8,779.
Refined products:			
Light distillate	5,050	5,475	United States 3,390; United Kingdom 1,198; Australia 428; Philippines 214; South Africa 98; Uruguay 71.

COMMODITY REVIEW

NONMETALS

Cement.—Kuwait imports relatively large quantities of cement, although it has some limestone resources which might be adequate for cement manufacture. A feasibility study on the production of cement in Kuwait was underway in 1963. An alternative plan, by which Iraq would build a cement plant near the Kuwaiti border (at Jebel Sanam) with all production going to Kuwait, has also been proposed.

MINERAL FUELS

Crude Oil.—The Kuwait Oil Co.'s record petroleum production in 1963 came from 7 fields containing a total of 445 production wells, 35 of which were brought into production during the year. The Burgan field produces most of Kuwait's oil from Cretaceous sands at depths of 3,500 to 4,500 feet. It had 308 production wells at the end of the year, followed by the Magwa field with 53 wells; Ahmadi, 35; Raudhatain, 27; Minagish, 10; Sabriya, 7; Umm Gudair, 4; and Bahra, 1. An additional six wells had not been connected to production facilities by December 31.

In KOC drilling operations, 23 exploration wells and 28 development wells were completed during 1963, and 5 wells were being drilled at the end of the year. Of the development wells completed, 18 were drilled in the Burgan field and 8 at Magwa. At Minagish, where oil is produced from the Ratawi zone at 10,000 feet, two development wells were completed as producers in the Burgan zone at 6,500 feet. At Khashman, north of the Magwa field, a well drilled to test deep formations found no oil at depth but was completed as a producer in the Magwa zone at 5,000 feet. At the end of 1963 the company's proved petroleum reserves were estimated at 67,000 million barrels. No oil in commercial quantities has been found by offshore drilling, either by KOC which was drilling from an artificial island north of Kuwait City, or by Kuwait Shell which completed 3 wells in 1963 beyond the 6-mile limit.

Natural Gas.—Kuwait's gas reserves are estimated at 33 million million cubic feet.[3] Of the natural gas produced from petroleum operations, approximately 20 percent or 72,000 million cubic feet was utilized in 1962, the remainder being flared or vented. Of the total used, 45 percent was consumed in KOC operations; 25 percent was used for reservoir injection; 20 percent was delivered to government installations; and 10 percent was used in the manufacture of liquefied petroleum gas. Most of the gas received by the government was used for fuel in the water distillation and electric power plant at Shuwaikh port. Natural gas was also being used as fuel in sand, lime, brick-making, and asphalt-mixing plants and in an asbestos-cement plant which was commissioned in 1963.

[3] Oil and Gas International. V. 4, No. 1, January 1964.

Digitized by Google

Arrangements have been made with the Kuwait Oil Co. to supply an additional 75 million cubic feet of gas daily to the site of the government's planned industrial complex at Shuaiba. The Shuaiba development is primarily intended to exploit Kuwait's natural gas as a source of cheap industrial fuel and as raw material for petrochemical manufactures. The government has invited bids for construction of a port facility and for an ammonia plant with a capacity of 400 tons per day. Plans were also being considered for other chemical plants, as well as a steel plant and an aluminum smelter.

Petroleum Refinery Products.—The KOC refinery at Mina al-Ahmadi processed an average 203,000 barrels of crude petroleum per day during 1963. The plant's capacity was increased from 190,000 to 250,000 barrels per day by modifications to two distillation units. Production and storage facilities for liquefied petroleum gas were also increased and the quantity of LP gas exports rose by 75 percent over that of 1962.

Plans for construction of a government refinery, with a capacity of 80,000 barrels per day, were announced in late 1962 by the Kuwait National Petroleum Co. The refinery is to be located at Shuaiba, 27 miles south of Kuwait City.

The Mineral Industry of the Kuwait-Saudi Arabia Neutral Zone

By F. L. Klinger [1]

THE Kuwait-Saudi Arabia Neutral Zone was established by treaty in 1922 as a solution to the boundary problem then existing between Kuwait and the Arabian province of al-Hasa. The zone originally comprised a land area of roughly 2,000 square miles, but by application of the continental-shelf concept in 1949 its area was extended seaward to include some 2,400 square miles of the Persian Gulf. In these areas, Kuwait and Saudi Arabia each have an undivided half interest, and mineral concessions are negotiated on this basis. Commercial oil deposits were found on land in 1953 and offshore in 1960. Except for natural gas, no other mineral resources are known.

The Neutral Zone ranked fifth in petroleum production in the Middle East in 1963, accounting for 5 percent of Middle Eastern output. On the basis of posted prices, this production was valued at an estimated US$159 million.[2] Except for petroleum company requirements, all production was exported, with about one-fourth being partially refined before shipment. Government revenue from oil goes to both the Kuwaiti and Saudi-Arabian Governments; in 1963, total receipts were estimated to exceed US$40 million.

Three oil companies hold concessions in the Neutral Zone. Operations onshore and extending out to the 6-mile limit are jointly conducted by the American Independent Oil Co. (Aminoil) and the Getty Oil Co., which have equal shares in production. Areas beyond the 6-mile limit are leased to the Japanese-owned Arabian Oil Co. (AOC). Aminoil's concession is granted by Kuwait, the Getty concession by Saudi Arabia, and AOC has separate agreements with each country. Aminoil's agreement provides for payment to Kuwait of 57 percent of realized profits or 50 percent of the difference between posted price and cost of production, whichever is larger. In 1961 the Getty Oil Co. reportedly paid to the Saudi Arabian Government a royalty of US$0.55 per barrel with a minimum annual payment of US$1 million. Under AOC's agreements the company, in effect, now guarantees each government 28.5 percent of net profits, for a total royalty payment of 57 percent. Additional benefits are required when certain levels of average daily production are reached. The companies employed an estimated 1,500 persons in 1963.

The principal developments in 1963 were an increase of 120 percent in offshore petroleum production; an agreement by AOC to raise the

[1] Foreign mineral specialist, Division of International Activities.
[2] Actual sale value was somewhat less because of discounting.

Digitized by Google

Saudi Arabian Government's share of profits to equal the percentage paid to Kuwait; and boundary negotiations between the two countries. The Zone's land area is being divided for administrative purposes but this evidently will not change either country's half interest in the petroleum concessions; however, no settlement was reached on the problems of concession rights to offshore islands, nor on relocation of Kuwait's southern boundary. Also in 1963, AOC is believed to have relinquished 20 percent of its unexploited concession area to the Saudi Arabian Government.

PRODUCTION AND TRADE

A review of available estimates suggests that petroleum reserves in the Neutral Zone may be as high as 25,000 million barrels. Total Neutral Zone production averaged 315,000 barrels per day in 1963, an increase of 28 percent over 1962. New oil reserves were found on land, south of the Wafra field, and offshore at Khafji and al-Hout, 25 miles north of Khafji. The discoveries were made in the Ratawi limestone and yielded higher grade oil (33° to 36° API) than is now produced.

Refinery throughput in 1963 averaged 71,000 barrels per day in Aminoil's plant at Mina Abdullah (Kuwait), and 14,000 in the Getty refinery at Mina Saud. Both refineries produce only fuel oil and small quantities of naphtha. At Ras al-Khafji, AOC plans to begin construction in 1964 of a similar refinery with a capacity of 30,000 barrels per day.

The only recorded trade in mineral commodities in 1963 consisted of crude and refined petroleum. Of the total exports, including bunker deliveries, nearly 83 percent was crude oil.

COMMODITY REVIEW

MINERAL FUELS

Petroleum.—*Onshore.*—All onshore production comes from the Wafra field, which produced 16° to 26° API gravity oil from Eocene and Cretaceous strata at depths of 2,000 to 4,000 feet. Wafra production averaged 181,500 barrels per day in 1963 and accounted for 58 percent of all Neutral Zone production. At the beginning of 1963, 352 wells were producing and an additional 110 wells were shut in. In development drilling, a total of 185 wells was completed during the previous 2 years and an estimated 70 additional wells were to be drilled in 1963. Wafra reserves were estimated to be 6,500 million barrels in 1961.[3]

New oil reserves were found at South Fuwaris, 7 miles south of Wafra. Tests in 1963 on two exploration wells yielded 3,000 barrels of 33° API gravity oil per day from one well and upwards of 300 barrels per day from the other. The oil is produced from the Ratawi and Upper Jurassic formations at depths below 5,000 feet.

Offshore.—Offshore petroleum production accounted for 42 percent of Neutral Zone output in 1963. The average production rate of 132,300 barrels per day was 120 percent greater than in 1962. All of the 1963 production came from 37 wells in the Khafji field, which produces a relatively heavy crude (26° API) from two Cretaceous strata (Bahrain sands) at a depth of 5,400 feet. The Ratawi oil found at Khafji and al-Hout in 1963 is lighter (34° to 36° API) than the crude heretofore produced and contains half as much sulfur (1.7 percent). The new horizon was found 300 meters below the Bahrain sands. Total offshore reserves are estimated at 18,000 million barrels.[4]

Khafji production is expected to increase substantially in 1964. Highly automated gathering and loading facilities have been installed and the productive capacity of the field is now 210,000 barrels per day.

The Mineral Industry of Qatar

By F. L. Klinger [1]

IN RECENT years, Qatar has produced about 3 percent of the annual crude petroleum output of the Middle East. It ranked 6th in Middle East production and 10th in world petroleum exports in 1963. The country has no other known mineral resources except natural gas produced in association with crude oil, and construction materials.

Petroleum has been almost the only source of national income. Production in 1963 was valued at an estimated US$136 million, using Umm Said posted price, and provided 99 percent of all government revenue. Government revenues from petroleum, estimated at US$53 million in 1962, are obtained from three oil companies: Qatar Petroleum Co. (QPC), which accounted for all petroleum production until 1964; Shell Overseas Exploration Co., which now accounts for an estimated 10 percent of total production; and Continental Oil Co. (Conoco) which began explorations in 1963. These companies employed an estimated 3,500 persons in 1963, including about 2,000 Qataris.

PRODUCTION

All petroleum produced from Qatar through 1963 came from the onshore Dukhan field, operated by QPC. The offshore field of Idd al-Sharqi, discovered by Shell in 1960, was expected to begin production in 1964 and to account for about 10 percent of total Qatari production.

Dukhan production in 1963 averaged 191,000 barrels per day from

a total of 48 wells. This rate of production was 3 percent more than that of 1962 and was the highest since production began in 1949. The rate of production is now at a near-maximum level.

TRADE

All Qatar petroleum is exported except for approximately 500 barrels per day which is refined for local consumption. Petroleum exports in 1963 were valued at an estimated US$135.7 million, with the principal countries of destination being the United Kingdom, France, West Germany, and the United States. All exports were from Umm Said, 20 miles south of Doha, which is the terminus of a 55-mile pipeline from the Dukhan field.

Little information is available on imports into Qatar. In 1961, the value of all imports was US$45 million, with goods imported by QPC comprising 30 percent of this total. Imports of refinery products made up 2 percent of the total value. Qatar imposes a general import tax of 2½ percent ad valorem.

COMMODITY REVIEW

MINERAL FUELS

Substantial portions of the QPC and Shell concession areas were relinquished to the government during 1963, and in September, exploration rights in these areas were acquired by Conoco. QPC has now relinquished 7,700 square kilometers or 75 percent of its original concession, and Shell has released 13,000 square kilometers or 60 percent of its offshore area. The Conoco concession includes about 800 square kilometers of area south of the Dukhan field which QPC did not completely explore.

QPC expects to increase petroleum recovery by a program of gas injection and was building a compression plant in 1963. A problem of salt-water intrusion may also require remedial action. Dukhan crude, which is produced from Jurassic limestone at an average depth of 6,500 feet, is relatively light (41° API). In 1963 its posted price (US$1.95 per barrel) was the highest in the Persian Gulf area. The field was instrumented for fully automatic operation in early 1962.

The Shell offshore field at Idd al-Sharqi, located south of Halul island 50 miles east of Doha, is producing 25,000 barrels per day of 24° to 38° API gravity crude from Jurassic limestone at a depth of approximately 8,000 feet. Eight wells have been completed and have a combined productive capacity of 30,000 barrels per day. A converted tanker serves as a gathering and loading station, and exports were expected to begin in February 1964. A new field was discovered at Maydan Mahzam 20 miles north of Idd al-Sharqi.

Total petroleum reserves in 1963 were estimated to be approximately 3,000 million barrels.

The Mineral Industry of Saudi Arabia

By F. L. Klinger[1]

SAUDI Arabia has the second largest petroleum production of the Middle East and ranks fifth in world production. Its annual production has been about 6 percent of world output, and for several years the country has ranked third in world petroleum exports. As for other mineral resources, Saudi Arabia continued to produce a small quantity of cement and other construction materials and until 1954 was also a producer of gold and silver. Deposits of other metals and nonmetals are known to be present, but little is known of their economic potential.

The petroleum industry has dominated the national economy, providing almost all government revenue, foreign exchange earnings, and industrial employment. The value of crude petroleum produced in 1963 is estimated at US$1,000 million,[2] probably equivalent to 98 percent of the gross national product. The industry employed an estimated 11,000 Saudi Arabs, as compared with an estimated 800 engaged in quarrying and processing of construction materials.

The government obtained petroleum revenue under profit-sharing agreements with the Arabian American Oil Co. (Aramco), Trans-Arabian Pipeline (Tapline), and companies operating in the Kuwait-Saudi Arabia Neutral Zone. Under these agreements the government received at least 50 percent of company profits before foreign taxes. Government revenue from petroleum, which was equivalent to US$400 million in 1962, was increased by more than US$100 million in 1963 by settlement of two longstanding tax and royalty disputes between the government and the Aramco and Tapline companies and by accelerated income tax payments. Under these settlements, Aramco profits on oil exported to Lebanon are calculated on the higher posted prices at Sidon instead of at Ras Tanura, and Tapline agreed to begin transit-royalty payments.

GOVERNMENT POLICIES AND PROGRAMS

Government activities in the field of minerals increased during 1963. Under an agreement signed on March 24, the Arabian American Oil Co. relinquished to the government 65 percent of its exclusive concession area and all of its preferential rights in other areas. Petroleum exploration was being carried out in these areas by the government

[1] Foreign mineral specialist, Division of International Activities.
[2] Calculated from 1963 posted prices at Ras Tanura.

Digitized by Google

through its agency, General Petroleum and Mineral Organization (Petromin), which had been authorized to engage in all phases of the mineral industry. Under the March agreement, Aramco will progressively relinquish an additional 30 percent of its original concession by 1993. Petromin became a distributor of petroleum products early in 1964 after purchasing the Aramco bulk plant at Jiddah, and also planned to extend its activities into drilling, refining, and petrochemicals production.

In February, Saudi Arabia's first mining code was established. While asserting basic state ownership of all mineral deposits, the code appears to encourage private investment. Tax and royalty arrangements will be negotiated for each individual venture.

In September, exploration and development of mineral resources other than petroleum were accelerated by a technical assistance agreement with the U.S. Government. Saudi Arabian mineral resources are known to include deposits of base and precious metals, as well as magnesite, fluorite, barite, and large deposits of salt. With assistance from Aramco and the U.S. Government, geologic mapping of the country has now been completed on a scale of 1:500,000. The series of 22 maps is available to the public and includes a 1:2,000,000 geologic map of the country.

PRODUCTION

Production of both crude petroleum and refinery products was 7 percent greater than in 1962. Petroleum production averaged 1,629,018 barrels per day, an increase of 108,000 barrels per day as compared with 1962. Nearly 40 percent of the increase came from the Abu Hadriya field which began production in 1963. At the Ras Tanura refinery, daily throughput averaged 270,000 barrels, an increase of 20,000 barrels per day from 1962. Production of liquefied petroleum gases increased 100 percent as compared to the previous year.

TRADE

Virtually all Saudi Arabian exports are of crude petroleum and refinery products. Exports and reexports of other minerals and metals in 1961–62 (Hijrah 1381)[3] were valued at US$258,000, of which iron and steel products accounted for 99 percent.

Exports of crude petroleum in 1963 were 7 percent greater than in 1962, while refinery product exports increased by 19 percent. The estimated gross value of these exports was approximately US$1 billion,[4] of which crude oil accounted for 83 percent, and refinery products, 17 percent. Fifty-nine percent of all petroleum exports were by tanker from Ras Tanura; 30 percent by tapline to Sidon, Lebanon; and 11 percent by pipeline to Bahrain.

Imports of metals and minerals in 1961–62 were valued at US$30 million, or 12 percent of all imports. Iron and steel products were valued at 8 percent of all imports, followed by nonmetallic minerals (1.6 percent), mineral fuels (1.4 percent), and other metals (0.7 percent). Principal supplying countries (for all imports) were the United States, United Kingdom, Japan, West Germany, Italy, and the Netherlands. Imports from Communist countries were valued at 1.6 percent of all imports, the principal mineral product being 26,000 tons of cement from Rumania.

In early 1962 Saudi Arabia revised its tariff schedule—reducing or eliminating duties on most commodities but raising the duty on cement, gypsum, and marble. In December 1963, the tariff on gasoline imports was substantially increased. Petroleum products imported in 1962 and 1963 consisted of gasoline (about 4,000 barrels in each year), and lubricants (24,000 barrels in 1962 and 27,000 barrels in 1963).

TABLE 2.—Exports and reexports of petroleum and petroleum products[1]

COMMODITY REVIEW

METALS

There are iron deposits of possible commercial value at Wadi Fatima, 50 kilometers east of Jiddah, and at Wadi Sawawin, near the Red Sea coast about 200 kilometers south of Aqaba. The Wadi Fatima deposits consist of two layers of oolitic hematite from 1 to 5 meters thick; tentative estimates suggest that 60 million tons of material with an iron content of about 47 percent is available. At Wadi Sawawin, very large deposits of low-grade (30 to 35 percent iron) ferruginous sediments are found about 60 kilometers from the coast. Aeromagnetic surveys were carried out in this area in 1962, and ground exploration, sampling, and beneficiation tests are continuing.

At yearend, it was indicated that the government soon would allocate funds for construction of a steel products rolling mill at Jiddah. The plant would operate on imported steel pellets and have an annual capacity of 45,000 tons of steel-reinforcing bars and sections.

NONMETALS

In 1962, two cement plants were operating in Saudi Arabia; one at Jiddah, with an estimated daily capacity of 450 tons, and one at Hofuf near the oilfields, with a daily capacity of 300 tons. A third plant may be built at Riyadh. A gypsum plant with a capacity of 100 tons per day began production in Riyadh in late 1961, and two lime plants have been operating near Dhahran since 1962. The marble industry is based at Jiddah, with numerous small quarries located east of the city at Wadi Fatima. The lime plants near Dhahran and the cement plant at Hofuf are fueled by natural gas and consumed a total of 530 million cubic feet in 1963.

MINERAL FUELS

Aside from the revenue and concession agreements of March 24, the principal developments in the petroleum industry during 1963 were the entry of three new fields into production, the discovery of a new offshore field (Abu Safah) and additional onshore reserves at Qatif, and expansion of production facilities for both crude petroleum and refinery products.

Petroleum produced in 1963 came from 247 wells in 9 fields. The Ghawar field accounted for 47 percent of total production, followed by Abqaiq (23 percent), Safaniya (18 percent), Khursaniyah (4 percent), and Abu Hadriya (2.5 percent). Total production was 39 million barrels more than in 1962 and 88 percent of the increase was produced from Ghawar and Abu Hadriya fields. Abu Hadriya, tested for 3 days in 1962, began regular production in 1963 and produced 15 million barrels. Two other new fields, Fadhili and Khurais, began production in 1963 but did not contribute significantly to total production.

Digitized by Google

A new offshore field, Abu Safah, was discovered 27 miles northeast of Ras Tanura, and delineation of the field began in September. Abu Safah lies within an area covered by an agreement whereby petroleum revenue will be shared between Saudi Arabia (75 percent) and Bahrain (25 percent). In the Qatif field, 30 miles southwest of Abu Safah, new oil reserves were found below the Arab D member, and the (northern) extension of the field was proved by delineation drilling. The first offshore well of the Qatif field was being drilled at the end of the year.

Seventeen wells were drilled during the year, including 10 development wells, 1 exploration well, and 6 for stratigraphic or observation purposes. Three wells were drilling at the end of the year. At the end of 1963, proved liquid hydrocarbon reserves were estimated to be 57,800 million barrels, and gas reserves were estimated at 24,096,000 million standard cubic feet.

In 1963 the productive capacity of the Safaniya field was increased by 9 percent to 425,000 barrels per day, and the Manifa field, with an initial capacity of 100,000 barrels per day, was being prepared to start production in 1964. Both of these fields are offshore. Onshore, the Ghawar field capacity is scheduled to be increased by 159,000 barrels per day in 1964 with completion of additional wells at 'Ain Dar and a 65-mile pipeline connecting the southern (Haradh) part of the field to existing facilities. At the Ras Tanura refinery, capacity of the refrigerated liquefied petroleum gas plant was tripled to 12,000 barrels per day in 1963, and a new crude stabilization plant (for removal of hydrogen sulphide) with a capacity of 170,000 barrels per day was nearly completed at the end of the year.

In longer range plans, the productive potential of the Ghawar and Abqaiq fields was being increased by injections of water and gas. Average daily injections during 1963 included 300,000 barrels of water, 20,000 barrels of liquefied petroleum gas, and 250 million cubic feet of gas. At Ras Tanura, a new marine loading facility, scheduled for completion in 1965, will increase the crude oil shipping capacity of the port by 500,000 barrels per day.

The Mineral Industry of the Federation of South Arabia[1]

By F. L. Klinger[2]

THE Federation of South Arabia, including Aden and 11 other States, covers the western 60,000 square miles of Aden Protectorate. Aden is the only part of the Federation having significant mineral production or trade, and is one of the world's largest bunkering stations, supplying fuel to about 6,000 ships annually. It is also the principal port of entry for all goods (including minerals and metals) into Yemen.

The mineral industry consists of petroleum refining and production of salt from sea water. Petroleum products account for more than 99 percent of the value of mineral production, and the trade in petroleum and petroleum products accounts for 60 percent of the value of all trade. The mineral industry is probably the largest single source of government revenue other than subsidies and provides additional port revenue from bunkering services. Employment is estimated at 2,100 in petroleum refining, 1,400 in bunkering operations, and 300 in the local salt industry. The principal employer is British Petroleum (Aden), Ltd., which operated the area's only refinery and accounted for most bunkering sales.

Aden's accession to the Federation in January 1963, shifted responsibility for commerce, industry, banking, and currency to the local government, but was not expected to appreciably alter mineral production or trade. The principal development in the field of minerals has been the expansion of the Aden refinery. Other developments include a British mineral survey in the protectorate area completed in 1962, which found no deposits of economic value, and the start of construction of three "dolphin" berths at the port, which will increase cargo handling capacity as well as reduce tidal restrictions on ship movements.

The East Aden Protectorate covers 75,000 square miles between the Federation of South Arabia and the Dhofar Province of Muscat and Oman. This area has a subsistence-level agricultural economy, and there is no industry or mineral production aside from local quarrying of construction materials. Government revenue, estimated at US$2 million annually, is mostly obtained from customs duties, subsidies from the British Government, and petroleum concession rentals; the latter totaling about US$350,000 in 1963.

[1] Includes information on the East Aden Protectorate.

PRODUCTION

In 1963 the estimated gross value of mineral production and processing in Aden was US$148 million, of which petroleum products accounted for 99.9 percent, and salt for 0.1 percent. Refinery production in 1963 was 10 percent more than in 1962 and resulted from increased production of fuel oils. Output of residual fuel oil increased 19 percent, and diesel oil, 7 percent. Fuel oils accounted for 74 percent of refinery production in 1963 and 70 percent in 1962.

TABLE 1.—Production of minerals[1]

Commodity	1959	1960	1961	1962	1963

[1] All recorded production is from Aden.

TRADE

Exports of petroleum products (excluding bunkers) in 1963 were valued at an estimated US$84 million or 44 percent of all exports. This was a 10-percent increase in value over that of 1962. In terms of value, 35 percent of the petroleum products exported in 1963 were destined for the United Kingdom. An additional 11 percent was consigned to Japan and about 5 percent each to Singapore and Australia. As compared with 1962, the value of exports to Japan increased sixfold to about US$10 million.

Bunker loadings in 1963 totaled 3,847,000 metric tons, valued at US$65 million or 34 percent of all exports. This was a 9-percent increase in volume but a 3-percent decrease in value compared with 1962. British Petroleum supplied 73 percent of all bunker loadings; Mobil Oil (East Africa), Ltd., 17 percent; and Caltex Oil (Aden), Ltd., 10 percent.

Mineral and metal imports in 1963 were valued at an estimated US$122 million, about 45 percent of the value of all imports, compared to US$113 million in 1962. Crude petroleum accounted for an estimated 34 percent of the value of all imports, followed by petroleum products (10 percent), iron and steel (0.8 percent), and cement (0.6 percent). These proportions were not appreciably different from 1962 although imports of fuel oils increased by more than 50 percent and accounted for the increase in total value.

In 1963 substantial changes took place in the total value of imports of crude oil and petroleum products from the principal supplying countries. The value of imports from Iran increased about 40 percent while those from Kuwait fell nearly 25 percent. Shipments

Digitized by Google

from Iraq and Bahrain more than doubled in value but decreases of 30 percent were reported for Qatar and the Trucial Coast.

Imports of cement and products of iron and steel, which rose sharply in 1961 as civil and military construction projects began, were expected to remain at relatively high levels through 1964.

COMMODITY REVIEW

NONMETALS

Salt.—All production was from the Indo-Aden Salt Co., the last of four salt companies formerly operating in Aden. During the 1950's, the combined annual output of the four companies was nearly 400,000 tons per year. The closing of the other firms and the reduced level of Aden's output is due to a sharp decline in Indian salt imports and to subsequent intensified competition for Japanese markets.

Digitized by Google

MINERAL FUELS

Petroleum.—Refinery improvements and expansion begun in late 1960 have increased capacity of the Aden refinery from 120,000 to 136,000 barrels per day. The refinery, established in 1952, processes only imported crude. During 1963, it operated at 95 percent of rated capacity, compared with 89 percent in 1962 and 73 percent in 1961.

Petroleum exploration was being conducted in the East Aden Protectorate by the American International Oil Co. (formerly, Pan American Oil Co.) a subsidiary of Standard Oil Co. (Indiana). Exploratory work completed in 1963 included 24 party-months of surface geological surveys and 7 party-months of seismic surveys. No drilling activity was reported.

The oil rights in this area were originally held by Petroleum Concessions, Ltd., a subsidiary of Iraq Petroleum Co. (IPC), but were relinquished in 1960. The Hadhramaut concession, covering the western three-fifths of the protectorate, was acquired by American International from the sultans of Qu'aiti and Kathiri in 1961. The Mahra concession, adjoining Dhofar, was acquired in 1962 from the Sultanate of Qishm and Socotra and includes 2,000 square miles of Socotra Island. Both concession agreements include a 10-year exploration period, a 30-year development period and provide that the Sultanates receive 55 percent of net profits as well as participation rights of up to 20 percent.

The Mineral Industry of the Syrian Arab Republic

By F. L. Klinger [1]

SYRIA is essentially an agricultural country but produces petroleum products, cement, salt, glass sand, gypsum, and other construction materials. The country also has unexploited reserves of phosphate rock, petroleum, and natural gas.

Petroleum refining and cement production were the most important mineral activities in 1963. Value of petroleum products and cement produced in 1962, the last year for which complete production data are available, was estimated at S£107 million,[2] equivalent to US$28.3 million. This was about 4 percent of the gross national product and 99 percent of the value of all mineral products.

Government revenue from mineral activities amounted to S£127 million (US$33.2 million) in fiscal year 1961–62. Petroleum transit royalties accounted for 85 percent of this total and continued through 1963 to supply a substantial share of Syrian foreign exchange earnings. Transit royalties are derived from the crude petroleum shipped across Syria through pipelines of the Iraq Petroleum Co. (IPC) and the Trans-Arabian Pipeline Co. (Tapline).

IPC pipelines also supplied crude to the Government refinery at Homs. This refinery, with a capacity of 1 million tons a year (about 20,000 barrels per day), was completed in 1959 and supplies about 75 percent of Syrian demand for petroleum products. The value of crude petroleum delivered to the refinery in 1961–62 is included in the figure for Government revenue.

It is estimated that 7,000 persons were employed in all mineral-based industries in 1963. About 500 were engaged in direct production of minerals, with 1,250 in cement and glass manufacture, and 5,300 in petroleum transport and refining.

PRODUCTION

Production gains were realized or predicted in most mineral commodities in 1963. The gross value of mineral products in 1962, the last year for which complete data are available, was estimated at about US$28.5 million, of which petroleum products and cement accounted for about 59 percent and 40 percent, respectively.

[1] Foreign minerals specialist, Division of International Activities.
[2] Syria's official monetary unit is the Syrian pound. The official exchange rate is 3.82 Syrian pounds equal US$1.00.

[3] Estimate.

TRADE

Practically all metal, industrial mineral, and commercial fuel requirements of Syria must be met by imports, which in 1962 were valued at US$49.7 million and constituted 22 percent of all imports. Iron and steel products were the most important group with 12 percent of all imports, followed by mineral fuels (7 percent), nonmetallic minerals (2 percent) and nonferrous metals (1 percent).

Mineral and metal exports were valued at S£7 million, 1 percent of the value of all exports. Gasoline represented more than 90 percent of this value.

Compared with 1961, imports of iron and steel doubled in 1962 because of increases in light constructional items, and aluminum imports were up 60 percent owing to a 600-ton increase in ingots. Imports of most other nonferrous metals were not appreciably changed.

Of mineral fuel imports, valued at US$15 million, crude petroleum accounted for 68 percent and petroleum products (largely distillate fuel oil) for 31 percent. Mineral and chemical fertilizers made up 65 percent of total nonmetal imports, which were valued at about US$5,236,000. Imports of combined fertilizers (phosphate-nitrate-potash) increased five times over that of 1961 while others decreased 30 percent.

Tariff regulations remained unchanged. For the most part, Syria has a single-column tariff but gives preferential treatment to many commodities imported from Arab States. Syrian tariffs and taxes on imported commodities aggregate 25 to 30 percent of import (c.i.f.) value. A new regulation, effective in January 1964, will permit issuance of import licenses only after a percentage of c.i.f. value of import shipments is deposited. The rate is 15 percent for mineral commodities (including mineral fuels) and 40 percent for metals.

COMMODITY REVIEW

METALS

Iron and Steel.—Iron deposits near Radjou, formerly regarded as a source of raw material for a Syrian iron and steel industry, now appear to be uneconomic because of their low grade (25 percent iron) and unfavorable metallurgical properties.

A small quantity of iron and steel scrap is consumed by Syrian industry each year. Comparison of import and export statistics indicates the following quantities available for use or stockpiling: 1961, 2,453 tons; 1962, 1,757 tons; and 1963, 3,006 tons.

NONMETALS

Cement.—Cement production has risen steadily over the past 5 years and this trend is expected to continue. In 1963 an Aleppo firm intended to double its daily capacity to 600 tons, and a new plant with a capacity of 300 tons per day may have been nearing completion at Homs. Total productive capacity of Syrian cement plants in 1963 was estimated to be at least 700,000 tons per year.

Fertilizers.—During the past 5 years, sedimentary phosphate deposits southwest of Palmyra have been extensively drilled and sampled. Proved reserves, under a maximum of 20 meters of overburden, are estimated at 15 million tons containing 28.5 percent P_2O_5 (Kneifis deposits) and 60 million tons containing 24.5 percent P_2O_5 (Eastern deposits). Large additional reserves are indicated in the Eastern field. In 1963 the Government awarded a contract to Western Knapp Engineering, Inc., to investigate the requirements for production of superphosphate and beneficiated phosphate rock from these deposits.

A nitrogenous fertilizer plant was under construction at Homs during 1963. The plant is to have an annual capacity of 110,000 tons of lime ammonium nitrate, but initial production was not expected to begin until 1966.

Glass Sand.—Glass sand deposits near Al Mazzih are the principal source of raw material for the Damascus glass factory, but production from these deposits is not reported by the Government. The factory has an annual capacity of 10,000 tons of glass and supplies most of Syrian requirements as well as sheet glass for export.

Salt.—Extensive new salt deposits have been found near the Euphrates River near Deir es Zor. The best deposit is a layer 14 feet thick, estimated to contain 13 million tons of high-quality salt. The deposit may be difficult to exploit economically, as it is found at a depth of 130 meters.

MINERAL FUELS

Petroleum.—The Karatchok-Soueidia oilfields of northeastern Syria have been under development since 1959. By 1963, recoverable reserves were estimated at 1,250 million barrels and development drilling had brought in at least 16 producible wells having an estimated total production potential of 27,000 barrels daily. Three additional wells were being drilled at the beginning of 1963. The oil is found in Cretaceous

Digitized by Google

limestone at depths of 5,000 to 7,000 feet; its API gravity ranges from 20° to 24°, and its sulfur content exceeds 4 percent.

Production has been delayed by inadequate transportation facilities. At the end of 1963 the Syrian General Petroleum Authority was supplying detailed specifications for construction of a 22-inch pipeline from the oilfields to the port facility being constructed at Tartous, a distance of about 650 kilometers. This port is to be ready for shipping in 1966. Early in 1963 the Government was considering construction of a new refinery at Tartous to refine Syrian crude; however no action was taken. Instead, by yearend, plans had been formulated to expand the capacity of the Homs refinery to 1.7 million tons per year (about 34,000 barrels per day). Also under consideration was the establishment of a small refinery and the development of a petrochemical industry in the Karatchok area under the second 5-year plan (1965–69).

The Homs refinery operated at 83 percent of rated capacity in 1963, compared with 77 percent in 1961 and 70 percent in 1960. In 1963, contracts were let for construction of a 512-kilometer, 6-inch products pipeline from Homs to Damascus, Aleppo, and the port of Latakia, and at the end of the year the General Petroleum Authority announced that the pipeline to Aleppo and Latakia would be completed in early 1964.

Natural Gas.—An important but unexploited reserve of natural gas is in the Jibissa area, 45 kilometers south of Hasakeh and 100 kilometers northeast of Deir es Zor. Total reserve is unknown, but the potential yield from one well (Jibissa No. 1) is estimated at 24 million cubic feet daily of gas containing 92 percent methane.

The Mineral Industry of the Trucial Coast and Muscat and Oman

By F. L. Klinger [1]

TRUCIAL COAST

THE TRUCIAL COAST is the most recent addition to the petroleum-producing areas of the Middle East. Commencing production in 1962, the output of petroleum in 1963 exceeded that of Bahrain, and in 1964 the rate of production is expected to be the sixth highest in the Middle East. Other mineral activities in the Trucial States have been mostly limited to petroleum exploration; small tonnages of red ochre have been produced from an island off Sharajah, but no other mineral sources aside from construction raw materials are known. In most of this area, petroleum operations are the only means of industrial employment and provide all government revenues. Additional income is obtained by the State of Dubai from customs duties and a reportedly thriving traffic in gold.

MUSCAT AND OMAN

The Sultanate of Muscat and Oman (including Dhofar) covers an area of about 85,000 square miles along the southeast Arabian coast. The area has no mineral production or important industry. Small quantities of cement, salt, and petroleum products are imported but their aggregate value is estimated to be less than 5 percent of all imports. Government revenue, roughly estimated at US$1.5 million annually, is mainly derived from customs duties and petroleum concession rentals.

Since 1955, petroleum exploration has revealed oil deposits in three inland areas, two in Oman and one in Dhofar. None of these discoveries has proved to be of commercial value, mainly because the productive potential has not been sufficient to warrant construction of transportation facilities. Rumors persist, however, that commercial deposits were found in Oman in 1963.

PRODUCTION AND TRADE

Crude oil is the only mineral commodity produced in the entire area for which output data are available. All commercial production came from Abu Dhabi, largest of the seven Trucial States and the only one

[1] Foreign minerals specialist, Division of International Activities.

Digitized by Google

in which commercial petroleum deposits have been found. Cumulative production from 1962 to the end of 1963 was 23.5 million barrels. Using posted prices at Das Island this production was valued at an estimated US$42 million. Production in 1963 accounted for about 75 percent of this value.

In December, the output of petroleum from Abu Dhabi was more than doubled as production began from the onshore Murban field. By the end of 1963, petroleum operations had provided an estimated US$11 million in revenues to the Abu Dhabi Government and were providing employment for 3,000 persons.

Exports of petroleum from Abu Dhabi, assumed to be equal to the volume of production, were valued at an estimated US$31 million in 1963 and US$11 million in 1962. Of the estimated value of all exports, petroleum comprised 68 percent in 1962 and 86 percent in 1963. Except for petroleum, Trucial coast exports consist mostly of reexports from the port of Dubai.

Imports in 1962 were valued at approximately US$20 million, of which petroleum products made up an estimated 4 percent. Although detailed figures are not available, gold bullion may account for more than 25 percent of the value of all imports.

TABLE 1.—Production of petroleum and imports of petroleum products

(Thousand 42-gallon barrels)

	1961	1962	1963
Production, Abu Dhabi: Crude petroleum	447	[1] 5,551	17,591
Imports:			
Gasoline	(2)	[3] 84	(2)
Kerosine	(2)	[3] 32	(2)
Distillate fuel oil	(2)	[3] 76	(2)
Lubricants	(2)	[3] 4	(2)

[1] Total production of 5,998,029 barrels is reported for the Umm Shaif field to Dec. 31, 1962, by AAPG. V. 47, No. 7, July 1963. Probably includes output from earlier production tests.
[2] Data not available.
[3] Estimate.

COMMODITY REVIEW

MINERAL FUELS

Petroleum.—*Abu Dhabi.*—The Trucial coast Umm Shaif field, 105 kilometers offshore and 80 kilometers southeast of the Qatar offshore development at Idd al-Sharqi, was being operated by Abu Dhabi Marine Areas, Ltd., owned two-thirds by British Petroleum Co. and one-third by Cie. Française des Pétroles. A medium-weight oil (34° API) was produced from Cretaceous and Jurassic limestones at depths of 5,500 to 8,800 feet. By the end of 1963, the field was producing 60,000 barrels of petroleum daily from 17 wells. An additional six wells were scheduled to increase the total productive capacity to 90,000 barrels daily by mid-1964. Umm Shaif production is remotely controlled from the export terminal at Das Island, 32 kilometers west.

Oil was found 80 kilometers southeast of Umm Shaif in the Zakum No. 1 exploration well drilled in 1963 by Abu Dhabi Marine Areas, Ltd.

Digitized by Google

The Murban field, 16 kilometers inland and 144 kilometers southeast of Umm Shaif, began production in December from 24 wells at an estimated aggregate rate of 80,000 barrels per day. Production was scheduled to increase to 120,000 barrels per day in early 1964 as a result of additional well completions. Extensive gathering, processing, and loading facilities completed in 1963 included four gas-oil separators having a total capacity of 200,000 barrels per day; three stripping columns for the removing of hydrogen sulfide by a hot carbonate process; a 112-kilometer, 24-inch pipeline from field to storage facilities at Jebel Dhanna; and two sea berths connected to Jebel Dhanna by 4.5-kilometer, 36-inch sea lines for gravity loading. Exports began December 15. The Murban field produces a relatively light crude (40° to 42° API), with a high H_2S content and a gas to oil ratio of 1,200 cubic feet per barrel, from Lower Cretaceous limestone at depths between 8,000 and 9,300 feet. No oil has been found in Jurassic strata equivalent to the Arab Zone reservoirs of Saudi Arabia and Qatar. Exploration and development work in the area is continuing.

A new field has been discovered at Bu Hasa, 25 miles southwest of Murban. Two wells were completed in 1963, and each was reported to have a production potential of 15,000 barrels per day. There is a possibility that the Bu Hasa field extends southward across the undemarcated boundary with Saudi Arabia.

Reserves were estimated at 7,000 million barrels at yearend,[2] compared with 6,000 million barrels at the end of 1962 and 1,500 million barrels at the end of 1961.[3]

Dubai.—About 125 miles east of the Murban oilfield, Dubai is the center of population and general trade on the Trucial coast. A minor boom in the local economy resulted from oil discoveries in Abu Dhabi and exploration activities in Dubai. Petroleum exploration was continued during 1963, and by early 1964 exploration drilling was expected to be underway at two locations, one offshore and one onshore. The wells were to be drilled by the Dubai Petroleum Co., a subsidiary of Continental Oil Co., which acquired the onshore concession and a half interest in the offshore concession in 1963. The onshore concession was formerly held by an associate of the Iraq Petroleum Co. but was relinquished in December 1962 after the drilling of an unsuccessful 12,000-foot well. Dubai Marine Areas, Ltd., owned by British Petroleum & Cie. Française des Pétroles, holds the other half interest offshore.

Other Trucial Coast States.—Petroleum concessions in the States of Sharjah, Ajman, and Umm al-Qaiwain were acquired in 1962 by John W. Mecom of Houston, Tex. In partnership with the Pure Oil Co., geophysical surveys of onshore and offshore areas of Sharjah were completed in mid-1963 and one well had been drilled to a depth of 5,358 feet at Abu Musa, 35 miles offshore, by the end of the year.

Petroleum concessions in Ras al-Khaimah were expected to be acquired in early 1964 by the Union Oil Co. of California. The concessions were formerly held by an Iraq Petroleum Co. subsidiary but were given up in 1960.

[3] World Oil. Aug. 15, 1963.

Digitized by Google

The Perkins Oil Co. of Wichita, Kans., was negotiating for concessions in the State of Fujairah during 1963.

Oman.—Petroleum Development (Oman), Ltd., formerly an IPC subsidiary but in 1963 owned 87 percent by Royal Dutch Shell and 13 percent by the Gulbenkian interests (Partex), found oil in the Yibal and Natih areas, 325 and 200 kilometers, respectively, southwest of the port of Muscat and about 360 kilometers southeast of Abu Dhabi's Murban field. Four wells were drilled at Natih in 1963, and testing was still in progress at the end of the year. The oil is found in Cretaceous strata below several thousand feet of Tertiary salt. No further details were available.

Dhofar.—The Dhofar concession, covering about 32,000 square miles in the southern part of the Sultanate, was acquired by John W. Mecom from Cities Service Petroleum Corp. and Richfield Oil Co. in 1962. These companies had drilled about a dozen wells and had discovered oil in 1955 at Marmul, 175 kilometers northeast of Salalah and about 80 kilometers from the coast. By 1958 four wells had reportedly been developed with a combined productive capacity of 2,500 barrels per day. Oil of several gravities (16° to 37° API) is found in Cretaceous strata at depths from 2,700 to 4,400 feet.

In partnership with the Pure Oil Co., Mecom had drilled five additional wells by early 1964. One well, Marmul No. 4, drilled to 3,500 feet, tested 150 barrels of oil per day; another, drilled 3,000 feet, reportedly flowed 500 barrels per day of 19° API crude and was located only 14 miles from the coast. Although the remaining wells were dry of oil, two of them found important supplies of fresh water.

The Mineral Industry of Turkey

By L. Nahai [1] and Clarence A. Wendel [2]

THE value of Turkey's crude mineral production in 1963 is estimated at US$150 million,[3] 4.2 percent more than in 1962. The value of crude minerals plus that of steel, blister copper, and cement (after deducting as far as possible the value of materials consumed in production of these commodities) is estimated to be 8.5 percent more than in 1962, and equivalent to 3.5 percent of gross national product (GNP) estimated at US$6.15 billion in 1963.

The country's first 5-year plan became operative on January 1, 1963. This plan aims at raising the GNP from the equivalent of US$5.8 billion in 1962 to US$8.2 billion in 1967, or by an average of 7 percent annually. According to the report of the State Planning Organization, the GNP rose by about 7 percent during 1963. Available information indicates that this rate of increase was maintained or somewhat exceeded by the mineral industry as a whole.

Construction of the Erĕgli steel mill continued during the year, and the Antalya ferrochromium plant began production in April; the plant was closed later because of lack of markets. Etibank, a State-owned economic enterprise with extensive mineral industry holdings, issued invitations to U.S. mining companies for proposals on a feasibility study for development of three copper deposits near the Black Sea coast under its concession. This organization also concluded arrangements for purchase of Polish equipment for a boron processing plant in the Marmara area. The Mineral Research and Exploration Institute reported progress in mapping and exploration programs. In areas closed to petroleum exploration by private industry, some 8,250 square kilometers were examined for petroleum prospects. Another 70,000 square kilometers were prospected for ores, lignite, and nonmetallic minerals, and 80,500 square kilometers for phosphate and radioactive minerals.

Discoveries in 1963 reported by the Director of the Institute included 4.5 million tons of iron ore, 38 million tons of bauxite and diaspore, 28 million tons of lignite, 13 million tons of low-grade phosphate rock, and uranium ores containing 330 tons of uranium.

During the year the Government established an international phosphate and chromium research center under an agreement with the Organization for Economic Cooperation and Development (OECD).

---

[3] In calculating this figure, half of the value of the blister copper produced was assigned to copper ore, for which a figure was not available.

Digitized by Google

The center reportedly is primarily to provide analytical and ore beneficiation research facilities and will not do more than incidental fieldwork.

In the fiscal year 1963 (ending March 31, 1964) the Mining Assistance Commission (MAC), through 20 agreements, granted loans equivalent to US$64,000 to private mineowners, bringing the total for the 3 years of its activity to US$347,100. The Commission, with a staff averaging 40 throughout the year, received 165 applications and performed 210 examinations. The MAC was established in 1961 by the Union of Chambers of Commerce, Industry and Commodity Exchanges of Turkey. Concurrently with its organization, TL10,000,000[4] (US$1.11 million) counterpart funds were supplied by the United States to establish two loan funds, a TL7,500,000 (US$833,000) Private Mining Risk Capital Fund and a TL2,500,000 (US$278,000) Private Mine Development Fund, to supply soft loans when the outlook for profitable development of a prospect or increasing in an existing mine seemed favorable.

GOVERNMENT POLICIES AND PROGRAMS

There were a number of Government actions in the field of minerals. A new Ministry of Energy and Natural Resources was created which assumed responsibility for administering a number of Government agencies and enterprises engaged in mineral activities including production. These include Etibank, The Mineral Exploration and Research Institute (Maden Tetkik ve Arama Enstitüsü—MTA), The Turkish Petroleum Corp. (Türkiye Petrolleri Anonim Ortakligi—TPAO), the Mining Department, the Petroleum Administration, Turkish Coal Enterprises (Türkiye Kömür Işletmeleri Kurumu—TKI), and the Atomic Energy Commission.

Etibank owns and operates the country's two copper mines and smelters, two major groups of chromite mines, a cupriferous pyrite mine, the country's largest colemanite deposit, the only sulfur mine and refining plant in Turkey, a small lead-zinc mine and concentrator, and a mercury mine. MTA is the agency concerned with geological survey and mineral exploration and the Mining Department administers the mining law and regulations. TPAO produces petroleum from fields discovered and developed by the Government and operates a Government-owned refinery. The Petroleum Administration administers the Petroleum Law of 1954. TKI produce all the bituminous coal and 60 percent of the lignite.

Remaining under the Ministry of Industry are the following: the Karabük Iron & Steel Works, at present the only primary producer of iron and steel; the Azot Sanayii T.A.Ş. (State Enterprise in the Nitrogen Industry) which produces nitrogen fertilizers; the government-owned cement plants; and Makina ve Kimya Endüstrisi Kurumu—MKEK (Machinery & Chemical Industries Organization) which, among other activities, operates steel and brass mills and appliance plants.

---

[4] The monetary unit of Turkey is the Turkish lira (TL). TL1=US$0.111.

Digitized by Google

In July, 60 articles of the Mining Law of 1954 were revised to facilitate its administration. Meanwhile, a U.S. consultant under contract to the Turkish Government prepared a draft for a new mining law but no legislative action was taken regarding the draft.

PRODUCTION

Production of most of the minerals used primarily by domestic consumers increased in 1963. Commodities registering gains included coal, lignite, crude oil, sulfur, and raw materials for cement and other construction materials (gypsum, clays, and limestone). Out-

put of most commodities produced to a significant extent for export declined; mercury and magnesite were notable exceptions.

Among mineral products, steel ingots registered significant increases in 1963 because of the new facilities at the Karabük steel plant. Copper metal output declined only slightly, and smelter lead production nearly tripled but was still relatively small. Refined petroleum product output gained appreciably.

TRADE

The value of mineral and metal exports (excluding petroleum products) fell from US$24,850,000 in 1962 to US$16,166,000, the lowest level since 1950. The ratio of the value of mineral and metal export, excluding petroleum products, to total exports continued the steady decline of recent years and in 1963 was only 4.4 percent, compared with 6.5 percent in 1962 and 7.6 percent in 1961.

[2] Includes iron and steel pipes.

Source: United Nations Commodity Trade Statistics, Statistical Papers, Ser. D, v. 12, No. 1–18; v. 13 No. 1–17.

Most of the decline resulted from a drop in the export of chromite, which was affected by Soviet chromite sales on world markets and slumps in United States and West European imports. Lower export of copper was caused by increased domestic consumption. Five major iron mines, under contract to supply ore to the Ereğli Steel Co., were contributing to Turkish iron ore stockpiles and did not enter the export market. Two iron mines in the Aegean area, which for a number of years had been operating for export, suspended operations because

Digitized by Google

their marginal-quality ore could not compete with high-grade ore available on the world market. These factors reduced export of iron ore. Shipment of high-grade, hand-sorted lead-zinc sulfied ores dropped because the producing mines shifted to development of less easily mined ore bodies than those exploited in the past 3 or 4 years.

Total value of imports was US$127,851,000 of which petroleum and its products accounted for 52 percent followed by iron and steel which accounted for 38 percent. The cost of importing the minimum petroleum requirements of the Turkish economy constitutes an important party of Turkey's adverse balance of trade which was US$241 million in 1962 and US$323 million in 1963.

TABLE 3.—Exports of metals and minerals

Petroleum refinery products:			
Gasoline	----------	41,855	West Germany 20,972; United Kingdom 15,198.
Distillate fuel oil	42,422	20,831	All to West Germany.
Residual fuel oil	497,468	674,398	United Kingdom 226,719; Greece 132,991; Netherlands 106,422; United Arab Republic 57,910; Ireland 53,419; Belgium-Luxembourg 50,246.

[1] Data not available.

Imports in all major categories except nonferrous metals increased. In the iron and steel category, steel ingots, wire rods, bars, and sections showed large increases. For petroleum, although the tonnage was larger, the value was less than in 1962 because a larger share of imports was crude petroleum.

COMMODITY REVIEW

METALS

Antimony.—As in 1962 Özdemir Antimuan Bakir İsletmesi produced all the antimony ore in Turkey from mines near Turhal. Results of the company's operation in the last 2 years in tons follow:

	1962	1963
Ore mined (3.5 percent antimony)	42,517	35,808
Sorted ore milled (5.0 percent antimony)	25,117	30,098
Concentrate shipped	1,440	1,805
Average antimony content—percent	62.45	61.66
Hand-sorted ores shipped	1,541	1,225
Average antimony content—percent	42.54	43.06
Regulus (99 percent antimony) produced	------	48

Rasih ve Ihsan was exploring an antimony-mercury prospect near Nigde, and 120 tons of ore were mined from exploratory work.

Chromite.—As exports declined stocks of chromite in Turkey increased to an estimated 500,000 metric tons, including off-grade ores. Many small mines closed and by yearend about 12 mines or mine groups owned by 8 companies were operating. With 110,271 tons output, Etibank was the largest single producer—77,939 tons from its mine in the Güleman area and 32,332 tons from Üçköprü mines. Sales by the company totaled 74,260 tons. Its concentrator at Güleman was inactive, but about 10,000 tons of ore from Üçköprü mines were treated in the Goçek mill of Türk Maadin Şirketi which is located near Etibank's mines. Sitki Koçman was the largest producer among private companies and accounted for half of exports by this section of the industry.

Compared with 1962, exports of chromite dropped 39 percent in tonnage and 50.8 percent in value (US$9,103,000 in 1962 and US$4,479,000 in 1963). As a result, value per ton in 1963 was only US$21 compared with US$26.55 in 1962.

It is estimated that of the exports, 50,000 tons was refractory and low-grade ore and about 163,000 tons were metallurgical. Exports of metallurgical grade chromite in 1963 were equal to about half of the quantity shipped in 1962. Of the 163,000 tons of metallurgical grade shipped in 1963, 55,000 tons were concentrates sold by Turkish producers who have European affiliates which produce ferrochromium.

The average value of US$11.80 per ton for shipment to Yugoslavia indicates that this material was off-grade or fines for concentration and possible use in manufacture of refractories. The remainder of the low-grade chromite was probably shipped to the United States.

F.o.b. prices of chromite (48 percent Cr_2O_3, 3:1 chromium to iron ratio) and of high-grade concentrate at yearend ranged between US$21 and US$24 per ton compared with US$28 to $29 in 1962.

To assist the industry, the Governments of United States and Turkey negotiated for a multilateral barter of U.S. agricultural commodities and Turkish chromite whereby about 150,000 short tons of chromite would be shipped to the United States (of which a third or less would be made into ferrochromium in the United States). The latter would ship agricultural commodities to countries with which Turkey has bilateral trade agreements, and these countries would ship goods to

Örko Krom	Harmancik	Concentrate	5,000
Bafka	Malatya area	Lump [1]	20,000

[1] Refractory.

Turkey in payment of the chromite shipped to the United States. Important criteria in the selection of third countries in the barter would be that shipment of agricultural commodities to that country would not displace normal commercial exports of these commodities to these countries, and that the transactions would have no adverse effect on the U.S. balance of payments. At yearend a barter agreement has not been signed.

Copper.—The drop in blister copper output resulted from smaller production at the Ergani mine where production of direct smelting ore and average grade of this ore declined. Of the blister copper output, entirely in the two mines of Etibank, 14,486 tons was sold domestically (11,692 tons in 1962). Principal recipients of copper were MKEK and Rabak Electrik Bakir ve Mamulleri. The latter has an electrolytic refinery at Kağithane with an annual capacity of 4,000 to 5,000 tons copper and copper alloy semimanufactures.

TABLE 6.—Salient statistics of copper mines

(Metric tons unless otherwise specified)

	Ergani		Murgul	
	1962	1963	1962	1963

[2] Data not available.
[3] Includes copper obtained from concentrates stockpiled in 1962.

Etibank requested new tenders for the construction of a flotation mill and smelter to treat low-grade Ergani copper ore which will constitute the bulk of future production of this mine because the high-grade ore is approaching exhaustion. The bank will utilize a US$8

Digitized by Google

million credit, originally granted by the Export-Import Bank in 1957, to finance the foreign exchange requirements of the plant. Etibank also issued invitations to mining companies and consultants for a proposal on a feasibility study for the integrated development of three copper deposits on the Black Sea coast (Küre, Espiye, and Murgul) under its concession.

Occurrence of copper disseminated in andesite in Zara was reported, but detailed information is lacking.

Iron Ore.—Divriği iron mine, which is a captive operation of the Karabük steel plant, produced 580,389 tons of ore and privately owned mines 166,202 tons. After producing 50,000 tons of ore, Büyü Eğmir mine stopped operation because of lack of export outlet. This mine presumably will start producing again to meet its contractual obligation to ship 75,000 tons of ore annually to Ereğli steel plant. Shipments to the Kangal, Çetinkaya, and Hekimhan railheads were for eventual shipment to Ereğli. East and West Hekimhan, Akdag, Oltukikise, and Çetinkaya are the principal mines which will supply iron ore to Ereğli. In 1964 these mines must deliver 228,000 tons of ore to this plant and, together with other mines, must increase shipments to 710,000 tons in 1965 and 800,000 tons by 1967.

Iron and Steel.—Production of pig iron, steel ingots, and coke at Karabük increased during the year. MKEK produced about 30,000 tons of carbon steel at Kirikkale using scrap. Metaş at Izmir is also reported to be producing 10,000 tons of steel per year from scrap.

TABLE 7.—Production and shipment of iron ore

(Metric tons)

Company	Mine	Shipments		Destination in 1963
		1962	1963	
Divriği	Türk Demirve Çelik	500,125	[1] 460,989	Karabük plant.
Kesikköprü	Kesikköprü Maden	87,000	80,000	Do.
Otlukilise	Demir Export (Koç)	40,792	11,000	Railhead, Kangal.

Miscellaneous			10,000	Karabük plant.
Total		790,049	628,924	

[1] Production reported as 580,389 metric tons.

The program inaugurated at Karabük in 1960 to expand steel capacity from 180,000 tons to 600,000 tons per year was nearing completion. A new sintering plant completed in 1962 increased the capacity from 225,000 to 700,000 tons of iron ore per year. Also in 1962, annual coke production capacity had been increased from 540,000 tons to 950,000 tons by the addition of a new plant with 3 batteries of 21 ovens each. At that time, byproduct recovery facilities were added to the 4 older batteries of 21 ovens each. These batteries produced 822,766 tons of coke in 1963 (512,656 tons in 1962). The third blast furnace (325,000 tons per year) was commissioned in December 1963 (after

Digitized by Google

a burnout in lining which occurred during the initial test in July was repaired), bringing total annual pig iron and hot metal capacity to 540,000 tons. In the steel melting shop, two new furnaces (150 tons per day) were being added to four existing open-hearth furnaces (75 tons per day), bringing total capacity to 600,000 tons per year. In the rolling mill section, extension of the 34-inch blooming and slabbing mill and reconstruction of the 28-inch section mill progressed; the 28-inch section mill may have been completed by yearend. Similarly, the erection of a continuous bar, wire rod, light section, and skelp mill was in progress during the year. This plant, which will produce yearly 230,000 tons of light sections with one-shift operation, is expected to be in operation sometime in 1964.

The Karabük plant is utilizing a US$15 million credit from the Export-Import Bank for further improvements and additions. The loan has already financed the construction of a water purification and pumping plant which was completed in March. Other additions will be a steel fabrication shop with 15,000-ton annual capacity (based on one-shift operations) and gray iron and steel foundries which will provide spare parts, ingot molds, rolls, and nonferrous castings.

Construction of the Ereğli iron and steel plant, being built with a US$129,600,000 loan from the U.S. Development Fund granted in January 1961, was on schedule, and certain units of the rolling mill are expected to be ready in 1964. The blast furnace will be blown in 1965 when 50-percent production capacity is expected; full capacity will be attained in 1968. The plant will have an initial ingot capacity of 400,000 tons per year which will be expanded to 1 million tons per year; it will produce mainly flat products.

Lead-Zinc.—Four private firms and Etibank worked lead-zinc properties during the year; only Etibank and Kurşun milled their ore to produce concentrates. Others produced hand-sorted lead-zinc ores which were shipped from Mersin to Imperial Smelting Co. in England or calcined products made by roasting zinc carbonate ores.

The concentrates produced by Etibank were not smelted in Turkey but Kurşun Sanayii shipped a lead concentrate with about 65 percent metal to a smelter at Darinca near İstanbul and produced 1,001 tons of metal. Of the remaining metal output, Mutler Battery Co. produced 780 tons in a small blast furnace in İstanbul. Lead is consumed principally for making batteries and for making ammunition including sporting ammunition.

Turkey also recovers lead from scrap. Production of lead from scrap increased substantially to 3,218 tons in 1963, compared with 722 tons in 1962. Annual consumption is estimated at about 5,000 tons.

During the year Rasih ve Ihsan began reopening the old Balya mines which were worked from 1910 to 1934 by Penarroya. There was also considerable exploration activity in the Zamanti River district by private companies. MTA has programed a major exploration program for lead and zinc for 1964.

Manganese.—Most mines were inactive during the year because easily mined reserves that could be worked economically at current prices were largely depleted. The bulk of the sales, which exceeded production, was probably obtained from working of old stocks.

Digitized by Google

Karabük contracted for a total of 24,000 tons of ore to be shipped in 1963 and 1964, but actual shipments to this plant are not known.

Mercury.—Sizma mercury mines near Konya were the leading mercury producers with an output estimated at 2,000 flasks. Etibank treated 18,270 tons of ore (reported average grade 0.268 percent mercury) from its Halikoy mine, which started operation in November 1962, and produced 763 flasks of mercury. Mercury recovery at Etibank's operation was low due to high stack losses and attempts are being made to improve the recovery.

The Mining Assistance Commission assisted in the establishment of a small retort plant near Manisa which produced 25 flasks in 1963. All mines in the old Karaburun area west of Izmir remained closed, and the Göksu mine near Kastamonu retorted mainly residues from previous operations which contained good metal values.

TABLE 8.—Lead-zinc producing mines and companies

(Metric tons unless otherwise specified)

Company	Mine	Ore milled	Grade (percent)	Production
Etibank	Keban	19,024	Zinc 6.4, Lead 4.5	1,110 lead and 1,867 zinc concentrate.
Kurşun Sanayii Ltd., Şirketi	Karakoca near Simav	12,210	Lead 9.4	2,000 lead concentrate.[1]
Rasih ve Ihsan	Cukurmaden and Akdağmaden.	(2)	Zinc 36–40, Lead 18	4,500 lead-zinc.
Saim Selim Budin Ltd., Şirketi	Kaleköy near Bakirdağı			
Karamanci Şirketi	Mines in Zamanti River district near Bakirdağı.	--------	(3)	4,000 calcined zinc ore.[4]

[1] This concentrate was smelted to produce lead metal.
[2] Ore is not milled but hand sorted.
[3] Data not available.
[4] Estimate, bulk of which was produced by Karamanci.

NONMETALS

Boron Minerals.—Although output of boron minerals declined by 23 percent from that of 1962, there was a 34-percent increase in exports.

The average declared value of boron mineral exports was US$29.30 per ton. Minimum export price set by the Turkish Mining Association upon authority delegated to it by the Ministry of Commerce was reduced to US$24 per ton f.o.b. Turkish ports.

Etibank's Hisarcik mine was the leading producer with 60,000 tons. This company also exported 43,125 tons of the total. Private producers were the Bortaş Türk Madencilik Şirketi and Türk Boraks Madencilik, a subsidiary of Borax Consolidated, Ltd.

Türk Boraks was producing trial lots from its Kirka mine (70 kilometers south of Eskisehir) and continued to recover ore from its Susuluk dumps. There was a new venture in boron mining. American Potash & Chemical Co. and the Fethiye Mining Co., one of the oldest chromite mining companies in Turkey, formed a joint venture called Cumek. Cumek purchased the Tulu mine of Rasih ve Ihsan Mining Co. located near Bigadiç as a partial source of colemanite ore for the new Subor plant in France pointly owned by American Potash and Ugine.

Digitized by Google

The application of Borax Consolidated, Ltd., to establish a boric acid plant at Susuluk was rejected by the Committee for Encouragement of Foreign Investments. Meanwhile, Eitbank concluded an agreement with Poland to design and erect a plant to process 35,000 tons of ore and produce 20,000 tons of borax and 5,000 tons of boric acid. The plant which will cost a total of US$1,200,000 in local and foreign currency is expected to be completed in 2 years and will be built on a site near Banderma.

Cement.—The upward trend in production and consumption continued with an increase of 16.1 percent in output and 15.5 percent in deliveries to the internal market which consumed 2,325,000 tons in 1962 and 2,686,000 tons in 1963, or a per capita consumption of 89 kilograms in 1963. Nominal capacity increased by 160,000 tons to a total of 2,670,000 tons with the addition of a privately owned wet-process plant in Konya; 1959 capacity was 1,960,000 tons.

Most Turkish cement was produced by the wet process and 43 percent was from privately owned plants. Almost all of the cement used domestically was shipped in bags. As in the last 5 years cement prices remained unchanged.

The industry employed 6,450 including 880 salaried employees.

Gypsum.—The largest gypsum mining operation in 1963 was that of Azot Sanayii T.A.Ş. atÜlukişla. This company's nitrogenous fertilizer plant 5 kilometers north of Kütahya used gypsum as a source of sulfur for production of ammonium sulfate. The gypsum was railed 600 kilometers to the plant site which had a rated annual capacity of 60,000 tons of ammonium sulfate, 50,000 tons of calcium ammonium nitrate, 6,000 tons of highly concentrated nitric acid, and 10,000 tons of technical ammonium nitrate, or a total of 30,000 tons of nitrogen per year.[5]

Magnesite.—Both production and export of magnesite increased, production by 83 percent and export by 216 percent. The calcining plant of the Austrian magnesite producer Radenthein went into operation at Eskişehir, and the plant of a subsidiary of Continental Ore Co. designed to produce 8,000 tons of caustic magnesia per year was under construction.

Phosphate.—Turkey's phosphate requirements was met by imports which increased substantially in 1963. Superphosphate output was 175,000 tons compared with 60,429 tons in 1962 and available capacity of 262,000 tons. Domestically produced sulfuric acid from the Murgul copper plant met a part of Turkey's requirement for superphosphate manufacture.

Exploration for phosphate deposits was accelerated after discovery of a phosphate horizon in 1962 by the Mining Assistance Commission in the Mazidağ (Denek-Mardin area) district. MTA reported extension of this to the northeast and south. New horizons, some less cherty than the originally discovered beds, were sampled and analyzed. Despite the establishment of a greater reserve of phosphate-bearing rock, reported grades are still too low to justify exploitation for making superphosphate. Calcining tests being conducted by MAC give promise of producing material for direct application to acidic soils

[5] Nitrogen, No. 18, July 1962, pp. 28–32.

Digitized by Google

such as those in the Black Sea area. MTA also reports encouraging results for calcining tests of low-grade rock.

Sodium Sulfate.—The sodium sulfate was recovered from brines of Tersakan Gölü and Bolluq Gölü southwest of Toz Gölü north of Konya and from Aci Göl east of Denizli. The MAC supplied technical assistance and a loan for sodium sulfate production.

MINERAL FUELS

In 1963 wood, either as fuelwood or charcoal, and animal waste accounted for about half of all energy consumed in Turkey, estimated at 20.5 million tons of standard coal equivalent. Coal and lignite supplied approximately 27 percent, petroleum products 19.5 percent, and hydroelectric power 5.5 percent of the total, compared with 33 to 34 percent for all commercial fuels in 1950. At yearend the country had an annual refining capacity of 4,850,000 tons of crude (100,000 barrels per day) and 1,330,000 kilowatts of electric power generating capacity.

Coal, Coke, and Lignite.—All coal and lignite mines owned by Türkiye Kömür Işletmeleri Kurumu (TKI) increased their output with the exception of the Soma mine. Coal requirements will increase when the Ereğli steel mill commences operation; it is expected that this plant will require 705,000 tons of coal annually. To meet this demand, Ereğli Kömür Işletmesi and Armutcuk Kömür Işletmesi, the subsidiaries of TKI that operate Zonguldak and Armutcuk fields, respectively, are equipping two shafts at Çatalagzi and Armutcuk to start hoisting in 1964. Equipping of the shafts is financed from a Development Loan Fund of US$14.5 million granted in 1959. Production from the entire Zonguldak Basin is scheduled to increase to 4.5 million tons of salable coal in 1966 and 4.7 million tons in 1967.

TABLE 9.—Solid fuels production distributed by mines and planned production

Digitized by Google

Coal sales increased notably to the Karabük steel plant where the coke ovens used 1,264,000 tons of coal compared with 785,000 tons in 1962. Sales to railroads continued a downward trend because more diesel locomotives were being used.

All the bituminous coal and lignite produced by the TKI was sold by its subsidiary, Kömür Satiş Tevzii Müessesi (Coal Sale & Distribution Organization). This organization attempts to place the high-grade fuels in the most essential markets. For this reason, retail sales of bituminous coal for space heating have been quite small compared with sales to industry and transportation. Some of the coal sold to industry is used for power generation so that the quantity of coal used for power generation is greater than that officially credited to thermal power plants.

Coal prices, set by the Government, have not been high enough to permit the Zonguldak mines to operate at a profit.

Coke.—Coke is produced at Karabük, Zonguldak (low-temperature), and at municipal gas works in Ankara, İstanbul, and İzmir. Of the total 1963 coke output, 822,766 tons was produced at Zonguldak. The Ereğli steel mill will have 74 ovens with capacity to produce 435,000 tons of coke per year.

TABLE 10.—Solid fuel sales[1]

(Thousand metric tons)

	1961	1962	1963

[1] Excludes sales of lignite produced in privately owned mines which in 1963 were probably as follows: Retail sales 859,000; sugar mills 112,000; cement plants 143,000; and small industry 71,000.
[2] Includes 9,000 tons exports.
[3] Includes 23,000 tons self-consumption.

Digitized by Google

Lignite.—TKI, through its subsidiary Garp Linyitleri Işletmesi (Western Lignite Operation), was the largest but not the sole lignite producer, as it was for bituminous coal. Private industry with numerous mines serving local markets produced 37 percent of total output in 1963. Of the four Government-owned mines, Soma is in Manisa district and the other three in the Kütahya Province. The bulk of output of Garp Linyitleri is used in larger powerplants, but a significant part of the production from Seyitömer is used by the nitrogenous fertilizer plant.

Petroleum.—As of December 31, 1963, 13 companies held 114 exploration licenses in Turkey covering an area of 5,230,368 hectares. The following were some of the companies with their respective areas: Türkiye Petrolleri Anonim Ortakliği (TPAO), 41 exploration licenses with a total of 1,957,919 hectares; Mobil Exploration Mediterranean, Inc., 24 with 1,167,962 hectares; Turkish Gulf Oil Co., 13 with 610,870 hectares; Compagnie d'Exploration Petrolière, 9 with 413,180 hectares; Pan Oil Co., 3 with 149,950 hectares; and N. V. Turkse Shell, 4 with 104,440 hectares.

In 1963, 41 party-months of geological fieldwork, 38 party-months of geophysical work, and 84,178 meters of drilling were carried out. The drilling was almost equally divided by length between development and exploratory drilling. Fifty wells were drilled (including four suspended wells). The wells were classified as 17 wildcats, 7 extension wells, and 27 development wells. Seven additional wells were drilling at yearend. Of the wells drilled, 30 were producers, 13 dry, 1 injection, and the remainder accounted for by suspended wells and others. TPAO, Shell, Mobil, and Tennessee Turkey, Inc., were the only companies engaged in drilling, having drilled 59,441, 12,783, 7,509, and 4,445 meters, respectively. Tennessee Turkey, Inc., drilled in Thrace on areas held by the American Overseas Petroleum, Ltd. (Amoseas), but the company abandoned drilling by yearend and terminated its drilling contract with Amoseas.

TPAO made a high-viscosity crude discovery near Çelikli in southeast Turkey, reportedly flowing at 1,100 barrels per day. Mobil continued its drilling activities in the Silivanka field where the company had already discovered oil in Cretaceous limestone. Shell discovered oil in Kürkan 1, 10 kilometers west of Kayaköy oilfield.

TABLE 11.—Petroleum production by companies and fields

Digitized by Google

Crude oil production increased by 25 percent during the year; TPAO remained the largest producer accounting for 82 percent of total Turkish output. Domestic production was equivalent to one-fourth of consumption, which has increased at an average annual rate of 11 percent during 1957 to 1963. Garzan-Gemirk field was the largest producing field.

Refining capacity stood at 4,850,000 tons per year (100,000 barrels per day), including Batman refinery—600,000 tons per year (12,500 barrels per day); Anadolu Tesfihanesi Anonim Şirketi refinery (ATAS—owned by Socony Mobil 56 percent, Shell 27 percent and British Petroleum 17 percent)—3,250,000 tons per year (65,000 barrels per day); and Instanbul Petrol Rafinerisi A.Ş. refinery (IPRAŞ—owned by Caltex 49 percent and Türkiye Petrolleri Anonim Şirketi 51 percent)—1,000,000 tons per year (21,800 barrels per day).

Refinery output was approximately 800,000 tons in excess of Turkey's requirements, mainly in residual fuel. Also during the year the Batman refinery could not dispose of all its gasoline. The Ministry of Commerce was given authority to control the entry of bonded petroleum products made of imported crude until the excess gasoline at Batman was disposed of, not only by the Government marketing firm Petrol Ofisi, but also by three foreign marketing firms—Mobil, Shell, and British Petroleum.

TABLE 12.—Production of refined petroleum by refineries

(Metric tons)

	1960	1961	1962	1963	Detail of products in 1963
Batman:					
Crude oil throughput	362,457	410,511	492,819	568,285	
Refinery output	325,826	371,012	451,860	532,535	Gasoline 77,311; solvent 1,598; kerosine 20,637; diesel 69,604; fuel oil 243,990; asphalt 119,395.
Izmit (Ipraş):					
Crude throughput	----------	219,295	935,433	990,205	
Refinery output	----------	174,172	842,380	888,941	Liquefied petroleum gas 11,155; gasoline 132,064; kerosine 95,674; diesel 249,633; fuel oil 400,415.
Mersin refinery (Ataş):					
Crude throughput	----------	----------	1,458,574	2,057,304	
Refinery output	----------	----------	1,338,951	1,977,289	Gasoline 331,749; kerosine 279,294; diesel 560,502; fuel oil 784,861; naphtha 20,883.

Crude oil imports increased by over 1 million tons to meet requirements of Mersin refinery which began operation in April 1962, but product imports were only 12.7 percent of those in 1962. Cost of crude and product imports were US$53.0 million and US$13.3 million, respectively.

In October 1963 the bilateral agreement between Turkey and the U.S.S.R. was revised to increase kerosine imports from US$200,000 to US $1,000,000. The Istanbul area experienced a kerosine shortage, partly as a result of the strike at ATAS refinery and increasing consumption.

Turkey exported 784,000 tons of crude products valued at about US$9 million. Included in the exports were 41,855 tons of gasoline shipped mainly to West Germany and United Kingdom and 674,000

Digitized by Google

tons of fuel oil shipped mostly to the Netherlands and United Kingdom. Bunker sales in the last 10 months of 1963 totaled 79,661 tons (49,793 tons in 1962).

TABLE 13.—Civilian consumption [1] of refined petroleum products

(Metric tons)

Product	1962	1963	Percentage change
Aviation gasoline	3,170	2,069	−34.7
Motor gasoline	510,218	515,737	1.1
Jet fuel	8,116	9,130	12.5
Kerosine	397,881	449,096	12.9
Motorine (gas oil)	735,355	875,465	19.1
Diesel oil	36,593	40,152	9.7
Residual fuel oil	383,661	538,561	40.4
Lubricants, grease	70,413	72,731	3.3
Asphalt	92,395	116,062	25.6
Solvents	979	1,455	48.6
Paraffin, vaseline	144	41	−71.5
Special preparations	1,394	6,787	386.9
Liquefied petroleum gas	1,740	8,766	403.7
Total	[2] 2,242,136	2,636,052	17.6

[1] Sales to distributors.
[2] Reported total; 77 metric tons not accounted for.

The prices of automobile gasoline, kerosine, and diesel fuel are set and controlled by Government decree. As of the end of the year, main depot sale (wholesale) price of gasoline (80 octane) and kerosine in U.S. cents per gallon were as follows:

	Gasoline			Kerosine		
	Retail price	Includes—		Retail price	Includes—	
		Duty	Taxes		Duty	Taxes
Mersin	38.20	4.67	20.06	17.42	1.46	5.99
İskenderun	38.61	4.67	20.13	17.78	1.46	6.05
İzmir	39.25	4.67	20.52	18.49	1.46	6.01
İstanbul	38.96	4.67	20.48	18.06	1.46	5.97
İzmit	38.03	4.67	20.01	19.34	1.46	5.94
Batman	39.26	4.67	20.11	18.06	1.46	6.02

To the wholesale price, the retailer adds his own transportation cost, evaporation and leakage losses, local taxes, and his profit margin. These markups differ in each locality, influenced mainly by inland transport charges. Gasoline pump prices in the main consuming centers of İstanbul, İzmir, İskenderun and İzmit were 41.34, 41.80, 41.17, and 40.92 cents per U.S. gallon, respectively.

The Government of Turkey reestablished the Liquid Fuel Price Stabilization Fund which had been allowed to lapse. Petroleum companies are now obliged to deposit into this special account an amount of money equal to reduction in world petroleum prices exceeding 5 percent which have not been reflected in domestic prices. World price of some products have fallen since June and July. Because prices in

Digitized by Google

Turkey have remained constant, petroleum companies are expected to have to deposit about TL11 million (US$1.22 million) into this fund. This fund will be used to insure the stability of the retail price of all petroleum products.

The production capacity of the fields of TPAO in District V exceed the refining capacity of Batman refinery, and TPAO requested bids for a 550-kilometer pipeline to connect the fields to İskenderun with an annual carrying capacity of 1.2 million tons per year.

The Mineral Industry of Afghanistan

By L. Nahai [1]

COAL, salt, lapis lazuli, and construction materials such as lime, gypsum, slate and stone were the only mineral commodities produced in Afghanistan during 1963. Beryl has been produced sporadically. Small deposits of chromite and lead-zinc are known but remained unexploited because there were no domestic markets for the two commodities and transportation costs from Afghanistan to world markets were too high. Oil fields of sufficient magnitude to justify exploitation have not been discovered, but known natural gas reserves are substantial and have potential significance. There is evidence of large high-grade iron ore resources, but these are in an unfavorable location.

The contribution of the mineral industry to the economy was small, although precise figures are not available. The reported value of mineral production in 1963 (excluding barite) was 181.6 million afghanis (about US$4 million). Employment in the industry, including cement plants and quarries, was estimated to be no more than about 2,000.

Although mineral activity in 1963 was small, planned investment in this industry during the second 5-year plan (1961–62 to 1965–66) [2] may total 10 to 12 percent of the total investment program. Significant projects in the minerals field under the plan include: (1) exploration and development of natural gas and petroleum fields; (2) installation of pipelines to bring natural gas (and possibly petroleum) to centers of consumption; (3) utilization of natural gas for production of nitrogen fertilizers; (4) expansion of coal production; and (5) possible establishment of an oil refinery capable of satisfying home demand (if domestic crude oil reserves are proven). It is the government's hope that by 1965–66 annual crude oil production will total 300,000 to 350,000 tons per year, coal output will be 170,000 tons, and a plant to produce 56,000 tons of nitrogen fertilizers annually will have been installed. The plan also provides for further survey of mineral resources (particularly iron deposits) and for the start of a steel industry. However, many problems regarding raw materials and transportation will have to be resolved before a steel industry can be established.

In November 1962, an agreement was signed by Afghanistan and the U.S.S.R. whereby the latter was to undertake surveys for coal, iron ore, gold, lapis lazuli, and beryl. The surveys will be part of the assistance to be rendered in support of Afghanistan's second 5-year plan. During 1963 German technical assistance to Afghanistan included geological work in the southern part of the country.

A petroleum bill, drafted some time ago, was considered by the National Assembly but apparently was not passed by yearend. Re-

[1] Near East-South Asia specialist, Division of International Activities.
[2] Afghan calendar year is Mar. 21 of 1 year to Mar. 20 of the succeeding year.

Digitized by Google

portedly, the draft would permit foreign capital participation in exploration and development of petroleum resources.

PRODUCTION

Output of Afghanistan's two most significant mineral industry products, cement and bituminous coal, showed significant gains in 1963 over that of 1962; 1963 production of both commodities was nearly three times that of 1959. Recorded salt production, however, fell to a level below that estimated for 1959, 1960, and 1962 and was only 38 percent of the reported peak of about 89,000 tons attained in 1961.

TABLE 1.—Production of minerals
(Thousand metric tons unless otherwise specified)

Commodity [1]	1959	1960	1961	1962	1963
Metals:

Briquets	[3] 22	[3] 20	19	[3] 19	[3] 20

[1] In addition to commodities listed, Afghanistan is also known to have produced limestone, marble, gypsum, clays, and talc, but data are insufficient to make any quantitative estimate of output.
[2] Data not available.
[3] Estimate.
[4] Data are for the Afghan fiscal year, Sept. 21 to Sept. 20.

TRADE

Afghanistan's first official trade statistics publication was released in 1963; the publication covers the Afghan calendar years March 21, 1956 to March 20, 1962. The country's mineral exports are insignificant. Lapis lazuli has been exported irregularly—about 1,000 kilograms in 1961–62 was shipped to West Germany and mainland China; a small tonnage of beryl was exported in 1957, but apparently none has been shipped since then. Value of imports by major classes of commodities for the 2 latest years reported was as follows:

Class	Value (thousand U.S. dollars)	
	1960–61 [1]	1961–62 [1]
Metals and metal manufactures [2]	3,121.1	2,210.5
Nonmetals and nonmetallic mineral manufactures [3]	4,290.4	3,285.7
Petroleum products	599.4	7,380.5
Total	8,010.9	12,876.7

[1] Year begins Mar. 21 and ends Mar. 20.
[2] Iron and steel, nonferrous metals, and manufactures of metals not described in detail.
[3] Lime, cement, building stone, building materials, clay construction materials, grinding and polishing wheels, glassware, pottery, etc.

Digitized by Google

Data on quantities of minerals and metals imported are available only in the case of petroleum products, which totaled nearly 450,000 barrels more in 1961–62 than in 1960–61.

TABLE 2.—Imports of petroleum refinery products

(Thousand 42-gallon barrels)

Commodity	1960–61 [1]	1961–62 [1]	Principal sources, 1961–62
Gasoline	480	807	U.S.S.R. 467; Iran 180; United States 85; Pakistan 65.
Kerosine	36	45	U.S.S.R. 25; Pakistan 13; Iran 6.
Diesel fuel oil	121	198	U.S.S.R. 109; United States 40; Pakistan 38; Iran 11.
Lubricants	14	50	U.S.S.R. 45; United States 3; Pakistan 2.
Total	651	1,100	U.S.S.R. 646; Iran 197; United States 128; Pakistan 118.

[1] Afghan calendar year; begins Mar. 21 of 1 year and ends Mar. 20 of the following year.

In 1961–62 mineral and metal imports constituted 13 percent of total imports; petroleum products alone accounted for 7.5 percent of all imports. In the same year U.S.S.R. accounted for 61 percent of Afghanistan's imports of gasoline, 56 percent of kerosine, 55 percent of diesel fuel oil, and 90 percent of lubricants. This significant reliance on the U.S.S.R. was partly because of the interruption of trade via Pakistan as a result of the closure of the Pakistan-Afghanistan border. On April 10, 1963, the Governments of Afghanistan and Iran signed an agreement whereby Afghanistan undertook to purchase 28,000 tons of petroleum products from National Iranian Oil Co. during the 12 months beginning April 21, 1963.

Afghanistan's mineral exports are insignificant. Lapis lazuli has been exported irregularly—1,000 kilograms in 1961–62 was shipped to West Germany and mainland China. A small tonnage of beryl was exported in 1957 but apparently none has been shipped since then.

COMMODITY REVIEW

METALS

Beryl.—A new beryl deposit was discovered in 1963 by a geological team of the U.S.S.R. operating in Afghanistan. The deposit is in the same general area north of Jalalabad, where beryl has already been mined, from time to time. Last recorded production was in 1960.

Iron Ore.—The iron ore of the Hagigak iron formation in the Hindu Kush Mountains, 120 kilometers northwest of Kabul, has been the object of much interest and speculation. Preliminary examination of these deposits during 1963 indicated reserves of rather high-grade hematite possibly exceeding 100 million tons, and estimates as high as 2,000 million tons have been cited without reference to grade. The deposits, however, are in a geographically unfavorable area.

Radioactive Materials.—In September the Afghan Government signed an agreement with the U.S.S.R. under which the U.S.S.R. undertook to build a small atomic research reactor at Kabul University. U.S.S.R. will provide fuel and additional equipment for experimental work and will train personnel in Afghanistan as well as in the U.S.S.R. It is expected that the reactor may become operational during the first half of 1965.

Digitized by Google

NONMETALS

Cement.—Production capacity of cement increased to 500 tons per day when the second 200-ton-per-day kiln started operation in the Ghori plant near Pul-i-Khumri. This plant already had a 200-ton-per-day kiln which began production early in 1962. Afghanistan's only other cement plant, one with a 100-ton-per-day capacity, was at Jabal-us-Seraj, 80 kilometers north of Kabul. It had been completed in 1957. Both plants, built with the assistance of Czechoslovakian technicians, use coal as fuel. The total 500-ton-per-day capacity of these plants is considered sufficient for domestic consumption.

MINERAL FUELS

Coal.—The bulk of 1963 coal output was obtained from the Karkar and Ishpushta mines, which have produced about 240 and 80 tons of coal per day, respectively. Karkar is about 15 kilometers north of Pul-i-Khumri, and Ishpushta is a similar distance northeast of Doab. These mines supplied Afghanistan's two cement plants and the Kabul area with coal. Another mine was being developed with U.S. assistance at Darra Suf, where Afghanistan's best coal resources are located. Work on this project continued during 1963. The Darra Suf area, which is 160 kilometers south of Mazar-i-Sharif and 640 road kilometers from Kabul, will eventually produce 150,000 tons of coal per year.

In December the cornerstone for a modern coal briquetting plant was laid at Karkar. The plant, which will utilize coal fines produced during mining, is of French manufacture and is expected to produce 8 tons of briquets daily starting in late 1964.

Natural Gas.—A new natural gas field, with 350 billion cubic feet reserves, was discovered at Yatime-Taq in the Shibarghan area of north Afghanistan. The new field together with Khwaja Gogirdak, which has an estimated 1,325 billion cubic feet reserve, give the country a total reserve of 1,675 billion cubic feet.

On October 18, the Governments of Afghanistan and the U.S.S.R. signed an agreement which will provide Soviet financial and technical assistance for the development and exploitation of the natural gas fields. Also under study are plans for laying pipelines to the Soviet border and to the site of the proposed Afghan fertilizer plant at Mazar-i-Sharif. Commencing in 1966, 70 billion cubic feet of natural gas will be produced annually of which three-fourths reportedly will be exported to the U.S.S.R.

The Mineral Industry of Burma

By K. P. Wang [1]

BURMA, long believed to be a rich mineral province, has been only a minor producer in recent decades, even by Far East standards. Its 1963 mineral output value of roughly US$45 million was far smaller than that of Thailand, Taiwan, and South Korea, countries not considered prominent in mining. The mineral industry is not of great consequence to Burma's predominantly agricultural economy; the value of minerals in 1963 was 3.5 percent of the gross national product. However, under British rule before World War II, mineral products were extracted at several times the present level and constituted a significant item in the county's export trade.

Burma's mineral industry has been concentrated in a few enterprises and mining districts. The leading mineral product, petroleum, came under control of the government enterprise People's Oil Industry, which took over the Burma Oil Company in 1963. A specific development during the year was the completion of a new oil refinery at Syriam near Rangoon. The Burma Corp. (1951), Ltd., producing lead, zinc, silver, and other metals at levels less than one-fourth of the historic peaks, was on the verge of becoming nationalized by yearend. The Government's Petroleum and Mineral Development Corporation (PMDC) planned in 1963 to reopen the Mawchi tin-tungsten mine, idle for many years except for small-scale tributary operations. The small Ywama steel mill in Insein near Rangoon continued to have problems with scrap shortages and high operating costs. The Thayetmyo cement plant increased production substantially without plant expansion, in order to take up the slack caused by import reductions. Plans were made to develop and nationalize the jade industry.

GOVERNMENT POLICIES AND PROGRAMS

March 1963 marked the first anniversary of the present government, which made clear its policy of neutralism in international affairs, minimum involvement with foreigners in industrial development, and nationalization of important enterprises. By the end of 1963, almost all of the leading mineral enterprises had become government operations. Foreign loans and grants and technical surveys from any source, including United Nations assistance and Japanese reparations, were welcome. However, foreign investment was neither encouraged

[1] Chief specialist, East Europe-Far East, Division of International Activities.

Digitized by Google

nor forthcoming, despite the shortage of domestic capital. A few international mineral and industrial consultants were employed, indicating the desire to utilize foreign know-how. The Government of Burma, while attempting to build up some industries, left little doubt that industrialization is not considered the basic tool in improving living standards for the country's 23 million inhabitants.

PRODUCTION [2]

The estimated US$45 million worth of minerals produced in Burma during 1963 comprised some $25 million of petroleum and natural gas products, $6 to $7 million of nonferrous base metals and byproducts, and $2 to $3 million each of tin-tungsten concentrates, iron and steel products, cement, and salt. The overall mineral output level rose only slightly during the last 5 years, with some items increasing and others declining. Thus, no significant progress has taken place in mineral exploitation.

Comparing production in 1963 with that of 1959, petroleum rose slightly because a little more crude oil came down the Mandalay River by barge without interference. Lead-zinc-silver output declined substantially midway in the 5-year period because of depletion of the very high grade ores from the Bawdwin mine; however, an upward trend began in the last 2 years. Tin output was nearly the same as that of 1962, whereas tungsten decreased owing to depressed world prices. Steel showed nominal advances, and salt hovered around a somewhat stable level. Cement attained a new output high in 1963, when capacity was more fully utilized.

Petroleum has been produced for domestic consumption only, with crude oil refined into the kinds of products needed by the economy. Steel, cement, and salt also have been produced for local use. On the other hand, virtually all the nonferrous metals and ores have been extracted for the export market, and lead and silver have been exported in the refined metal form.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:					
Antimonial lead (18 to 20 percent antimony) [1]	519	539	413	459	578
Antimony ore (40 to 50 percent antimony)	342	212	151	68	(2)
Copper matte (40 percent copper) [1]	384	365	279	370	431
Gold, refined troy ounces	212	304	194	(2)	(2)
Iron and steel:					
Iron ore	3,751	15,922	[3] 15,000	9,162	(2)
Steel ingot [3]	11,000	5,000	11,000	13,000	15,000
Rolled steel [3]	8,000	4,000	8,000	10,000	12,000
Lead:					
Concentrate lead (50 to 60 percent lead) [1]	34,518	32,107	29,007	33,449	[3] 36,000
Refined metal (99.99 percent lead) [1]	19,474	16,792	15,763	17,385	17,738
Manganese ore	550	294	178	193	(2)
Nickel speiss (20 to 22 percent nickel) [1]	433	332	650	536	462
Silver, refined [1] thousand troy ounces	1,728	1,501	1,325	1,498	1,511
Tin concentrate (68 to 72 percent tin)	1,069	1,060	1,047	924	[3] 615
Tin-tungsten concentrate (35 percent tin and 30 percent tungsten trioxide)	1,326	1,122	1,222	1,161	[3] 1,279
Tungsten concentrate (55 to 65 percent tungsten trioxide)	451	354	378	215	[3] 22
Zinc concentrate (54 to 56 percent zinc) [1]	19,372	18,028	13,122	15,119	14,924
Nonmetals: [4]					
Barite	1,016	1,626	2,039	4,048	(2)
Cement	36,202	44,901	39,570	53,282	124,130
Gypsum	1,956	1,052	853	2,084	(2)
Limestone	35,403	40,000	36,065	65,289	(2)
Marl	16,135	24,016	23,171	26,293	(2)
Salt	112,630	148,181	126,544	[5] 155,697	[3] 160,700
Mineral fuels:					
Coal	1,391	114	1,611	2,423	(2)
Natural gas million cubic feet	178	261	333	440	(2)
Petroleum:					
Crude oil thousand 42-gallon barrels	3,967	4,078	4,194	4,366	4,761
Refinery products: [6]					
Gasoline do	1,260	1,250	1,312	1,292	1,238
Kerosine do	818	687	718	702	854
Other do	768	882	1,260	1,229	1,280
Total do	2,846	2,819	3,290	3,223	3,372

[1] Output of Burma Corp. (1951), Ltd. All figures tantamount to national production; however, other companies sporadically produce small quantities of lead, zinc, and silver.
[2] Data not available.
[3] Estimate.
[4] Burma also produces a variety of semiprecious and precious stones, including amber, jade, ruby, sapphire, and spinel.
[5] Final figure; supersedes figure given in commodity chapter, volume 1.
[6] 1959–61 figures are for fiscal years, October to September of subsequent year. For 1962 and 1963, residua fuel is apparently not included and "Other" is comprised mainly of distillate fuel.

TRADE [3]

Although minerals were once important in earning foreign exchange for Burma and probably could be again, the benefit derived has been limited in recent years. Total mineral and metal exports approximated only US$10 million annually in 1962–63, equivalent to 3 percent of all exports, compared with 60 percent for rice. Burma produced a surplus of petroleum before World War II; it is now short of oil and exports only petroleum wax.

Imports of mineral and related products have steadily risen; the $40 to $50 million credited to this category in 1963 was nearly a fifth of all imports. By far the principal subcategory in the mineral field is metals and manufactures. The small steel industry of Burma was not even able to furnish one-tenth of the national requirements and

TABLE 2.—Exports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1962	1963	Principal destinations, 1962
Metals:			
Antimony ore	240	22	(1).
Copper matte	405	239	Japan, West Germany.
Lead:			
Ore (galena)	457	457	All to Japan.
Metal:			
Antimonial lead	336	494	All to India.
Refined	19,999	16,301	Mainly to India.
Nickel speiss	----------	423	Japan.
Silver bullion--thousand troy ounces	1,401	1,251	Mainly to United Kingdom.
Tin and tungsten:			
Tin ore and concentrate [2]	1,916	[3] 1,288	Mainly to Malaysia; also to United Kingdom.
Tungsten ore and concentrate	417	[3] 376	Mainly to Japan.
Mixed tin-tungsten concentrates	256	387	Japan; United Kingdom; Netherlands.
Tin ingots	26	(1)	(1).
Zinc:			
Ore	190	(1)	(1).
Ingots	(1)	50	(1).
Nonmetals: Salt	[4] 10,863	(1)	Mainly to mainland China.
Mineral fuels: Petroleum wax	10,896	11,202	Mainly to United Kingdom.

[1] Data not available.
[2] Includes several tons of bismuth-bearing concentrates.
[3] Incomplete. Exports from ports of Tavoy and Mergui, near the main tin-tungsten area, are not available.
[4] Year beginning Oct. 1, 1961, and ending Sept. 30, 1962.
Sources: Rangoon customs list, and Tavoy Chamber of Mines (tin and tungsten only).

TABLE 3.—Imports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	October 1961 to September 1962	Principal sources
Metals:		
Aluminum semimanufactures	2,800	Mainland China 1,200; United Kingdom 400; Hong Kong 300.
Copper semimanufactures	650	United Kingdom 240; U.S.S.R. 140; Japan 110.
Iron and steel semimanufactures:		
Iron ingots	2,628	Australia 1,999.
Joists	5,799	U.S.S.R. 2,214; Belgium 1,705; Japan 878.
Bars and rods	28,598	Japan 9,911; U.S.S.R. 8,563; mainland China 2,227.
Uncoated plates and sheets	14,315	U.S.S.R. 7,166; Japan 4,576.
Galvanized and corrugated sheets	30,050	Japan 13,638; Australia 12,960.
Tinplate	51,383	Japan 50,144.
Wire	4,143	Mainland China 1,427; Japan 1,199; U.S.S.R. 952.
Tube and fittings	10,737	United Kingdom 6,849; Japan 1,569.
Large pipes	4,372	Japan 2,661; Belgium 986.
Zinc semimanufactures	800	Australia 320; Northern Rhodesia 220.
Nonmetals		
Asbestos	347	Republic of South Africa 269.
Cement	166,121	Mainland China 50,283; United Arab Republic 16,920; Japan 14,245.
Fuller's earth	954	India 700.
Phosphate fertilizer	6,870	Japan 6,794.
Sulfur	1,938	United States 1,402.
Mineral fuels:		
Coal	268,577	Republic of South Africa 235,138.
Coal coke	8,065	All to Republic of South Africa.
Petroleum:		
Gasoline--thousand 42-gallon barrels	131	Iran 56; U.S.S.R. 44.

very few nonferrous metal manufactures were produced domestically. In 1962–63, annual imports of refined petroleum and coal each amounted to about $4 to $5 million, approximately, or 600,000 barrels of oil and 300,000 tons of coal. Imported refined oil represented about one-fifth of the 1963 supply; crude requirements for the second refinery may have to be met in large part by imports. Burma has the Kalewa subbituminous coalfield among others, but only nominal amounts of coal are produced and reliance on imports has been almost complete. About US$2 million of cement was imported in 1962; half this amount was imported in 1963.

COMMODITY REVIEW

METALS

Copper, Lead, Zinc, Silver.—For the Burma Corp. (1951)[4] the country's only important nonferrous base-metal enterprise, 1963 was a pivotal year. Production increased about 10 percent. In October, the company announced that reserves were 3 million metric tons, containing 11.2 ounces of silver per short ton, 15.1 percent lead, 9.2 percent zinc, and 0.85 percent copper ore; this was about 8 percent higher in combined metal content than the 1962 reserve. Improved metal prices were partly responsible for profits of 2.73 million kyats (officially, US$1 equals 4.72 kyats) during the 15 months ending September 1963, in contrast to losses of 3.27 million kyats reported for the financial year ending June 1962. However, the foreign partner (British and United States) of this joint venture did not derive much benefit because of high taxes and cumbersome regulations. In 1963, PMDC, the Government of Burma partner, was appointed sole agent for the sale of zinc.

A basic program to revitalize operations was under study by the corporation with US$667,000 worth of United Nations Special Fund technical assistance. Evaluation of reserves indicated there were large quantities of lower grade ores that could be mined profitably. Construction of a zinc smelter was also considered. Upon conclusion of exploration during 1963, a United Nations expert was sent to Bawdwin to investigate mining methods; this latter work was still in progress at yearend.

Iron and Steel.[5]—Attention was focused on the dwindling local scrap supply for the Ywama electric steel plant built with West German equipment by the firm DEMAG (Deutche Electrometallurgie Aktiengesellschaft). Utilization of imported high-price scrap was not considered feasible for the time being.

In 1963, the Ywama plant produced only about 8,000 tons of bars and rods (plus 4,000 tons of nails derived from them), approximately 4,000 tons of black sheet, and nominal quantities of wire products. Management was planning to expand sheet capacity and possibly add corrugating facilities.

[4] See company reports covering 1963.

Digitized by Google

Burma's iron and steel requirements had to be met primarily by imports. Actual consumption of major items in 1963 is estimated as follows: 60,000 to 70,000 tons of sheets and plates, mostly galvanized iron and tinplate; 15,000 to 25,000 tons of bars and rods; 10,000 to 20,000 tons each of tubes, pipes, and structural steel, and nearly 10,000 tons of nails.

Construction of an integrated iron and steel plant to satisfy existing demand has been under serious consideration for several years. At the invitation of the Government of Burma, Krupp of West Germany had undertaken a survey of the iron and coal potential and submitted its report in mid-1963. Since Burma has iron ore but no coking coal, the latest thinking was to construct a Strategic-Udy plant to use iron ore from Taunggyi, waterpower from Bahrchaung, and coal from Kalewa. However, this proposal was still most speculative in 1963.

Tin and Tungsten.—PMDC, with help of the United Nations expert, announced a development plan for the Mawchi tin-tungsten mine in 1963, involving geological investigation and rehabilitation and expansion of the mill. With PMDC scheduled to allot 1.5 million kyats from October 1963 to September 1964, it was hoped that production of mixed concentrates could be raised to 50 to 60 tons monthly during the first 3 years and 100 tons thereafter.

MINERAL FUELS

Petroleum.—Burma's oil industry became fully nationalized in 1963; the People's Oil Industry (POI) was designated as the managing corporation. The British Burma Oil Co. was fully compensated by the end of 1963, ahead of schedule. Exploration by foreign concerns was indefinitely deferred. Instead, plans were made to buy additional drilling rigs. The exploration program for 1963–64 would cost 35 million kyats (about US$7.3 million, at US$1 equals 4.72 kyats), approximately 3.8 million kyats more than actual expenditures in 1962–63. POI announced that it had made a 40-million-kyat profit in the first 9 months of 1963, compared with a 8.5-million-kyat loss in 1962. Apparently, faster extraction of known reserves and reduced salaries and wages to workmen contributed to this reported profit.

The second oil refinery at Syriam was formally opened on November 29, 1963. Rated at about 14,500 barrels per day, this unit is 2.5 times the size of the first Syriam refinery and has more than twice the capacity of the Chauk refinery. Domestic crude production was far short of the new throughput capacity, so that imports became necessary. Foreign crude was scheduled to come mainly from Indonesia, with the Indonesian Government and Caltex providing most of the oil. Thus, Burma, a crude oil exporter of some significance before World War II, became a net importer.

The Mineral Industry of Cambodia

By J. M. West [1] and K. P. Wang [2]

CAMBODIA, a country of about 6 million people and an estimated gross national product of US$650 to US$700 million,[3] had practically no mining activity in 1963 except a small production of gold. Salt sufficient for domestic consumption was extracted by evaporation of sea water. Phosphate rock deposits have been only intermittently worked for local use. Cambodia depended upon imports for small but increasing quantities of petroleum products, iron and steel, and cement. Technical assistance in mineral exploration was provided by the French and the Communist Chinese during 1963. Petroleum surveys made with the help of Polish and Soviet geological teams in 1960–62 apparently met with little success. Chinese aid resulted in the completion of a cement plant in Kampot Province in late 1963.

Cambodia's attempts to develop mineral industries have been seriously handicapped by the absence of domestic mineral fuels and the shortage of electric power. For example, plans to establish a small iron and steel industry in the northern part of the country, based upon local iron ores, reportedly had to be shelved in mid-1963 for lack of satisfactory fuel. Cambodia's total electric power generating capacity was only 65,000 kilowatts, and the modest goal of the 5-year plan, to end December 1964, was only 10,000 additional kilowatts.

A 50,000-kilowatt hydroelectric plant scheduled to be built in the Kamchay Gorge of the Tuk Chhon River in Kampot Province would relieve part of the longstanding power shortage. An agreement signed in Moscow in early 1963 by Soviet and Cambodian delegations provided a 12-year Soviet credit equal to US$11.4 million at 2.5 percent interest for this project. Construction with Soviet technical assistance was to begin in 1965. Cement for the project would be available from the newly completed cement plant, but copper wire for transmission lines and structural steel would have to be imported.

Trade deficits and inflation apparently slowed industrial development. The deficit in the first half of 1963 was US$4.3 million. U.S. economic aid, withdrawn in the fourth quarter of 1963, had provided about 10 percent of Cambodia's Government expenditures. The cost of living rose steeply during the year. Outlook for investment was obscure; guarantees of nonnationalization for 15 years were offered for new industrial enterprises.

PRODUCTION

Cambodia's mineral production during 1959–63 consisted mainly of gold and salt; some phosphate rock and nominal amounts of zircon and jet were produced intermittently. Gold output rose sharply despite dwindling reserves. Salt output has remained steady. Phosphate rock production was first recorded in 1962.

Phosphate rock.....do....	(2)	(2)	(2)	150	(2)

[1] Estimate.
[2] Data not available.

TRADE

Cambodia has no significant mineral exports; mineral import data reflect consumption levels. Mineral commodities constitute an important part of the country's imports; they aggregated one-fourth the total in value during 1963. Iron and steel products from Japan and mainland China, cement from Poland, the U.S.S.R., and China, and petroleum products from Indonesia were among the country's principal imports for the year.

A trade agreement was signed between Cambodia and North Korea near the end of 1963 for annual imports of US$1.4 million, comprising cement, coal, machinery, and various manufactured products. Additional cement imports valued at about US$1.1 million were expected from Poland and North Viet-Nam, owing to trade agreements made in October. Increases were expected in imports of aluminum sheets to replace galvanized sheets for construction and in bare copper wire to meet electric transmission needs. In 1963, Cambodia consumed nearly 1,000 tons of aluminum sheets and several hundred tons of copper wire. Cambodia's leading mineral import during the year was refined petroleum.

COMMODITY REVIEW

METALS

Iron and Steel.—In 1963, as in previous years, Cambodia relied on imports for iron and steel products. Development of a 4-million-ton reserve high-grade hematite-magnetite iron deposit near Phnom Dek in the Kompong area to supply a steel plant proposed to be built with Communist Chinese aid was actively considered until mid-1963. This 50,000-ton project for producing bars, rods, castings, and plates—the principal iron and steel products now imported—was temporarily abandoned because charcoal, the only available fuel, appeared to be too costly to use.

Nonferrous Metals.—During the last few years, most of the gold produced by Cambodia came from a single lode mine at Phnom Long in Lompong Thom Province. This mine, with rich ores and worked entirely by hand methods, once employed 1,000 laborers. The country also produced some placer gold from the Kompong Thom and Siem Reap areas. As of the end of 1963, all known goldfields in Cambodia apparently were nearing exhaustion in ore reserves.

During 1963, a search for bauxite by the French in the Lower Mekong Basin was unsuccessful.

Scattered occurrences of lead minerals are known in the Phnom Trek area, but no production has been reported. The Cadamones Range was reportedly considered worth further prospecting.

NONMETALS

Cement and Lime.—Cambodia's cement requirements, hitherto met entirely by imports, have been increasing. During the first half of 1963, more than 85,000 metric tons was imported. There have been

Digitized by Google

temporary lulls in demand, related to construction activities. However, the overall trend is upward.

A 50,000-ton-per-year cement plant at Chakrey Ting in Kampot Province, to be opened in early 1964, was intended to decrease imports. State-controlled, the plant was built with the aid of the Communist Chinese. The plant is coal fired, but plans have been made to convert it to oil.

Cambodia has adequate limekilns in Kampot Province to meet the country's needs. No statistics are available on output.

Phosphate Rock.—Mining of the Tumkias phosphate rock deposit in Kampot Province, where beds with estimated reserves of 120,000 tons of ore are worked in three separate hills, began in 1961. A processing plant with 12,000-ton annual capacity was proposed for a site at Tuk Meas in 1962. The ground product was expected to average 23 percent phosphorus pentoxide. Hitherto, almost all of Cambodia's fertilizer requirements have been met by imports.

Salt.—Salt was produced in 1963 by evaporation of sea water near Kampot, Ream, and to a lesser extent near Sre Umbell, in southern Cambodia. Small outcroppings of rock salt are widely distributed in several Provinces, but deposits have not been worked.

MINERAL FUELS

During 1963, French interests made a proposal to the Cambodian Government for the construction of a US$15 million oil refinery at Sihanoukville, with a stipulation that a 15-year marketing monopoly be included in any agreements. The plant would refine 8,000 barrels of crude oil per day from Kuwait—more than adequate to supply Cambodia's requirements for most petroleum products.

The Mineral Industry of Ceylon

By Charles L. Kimbell [1]

CEYLON's only significant contribution to world mineral supplies continued to be amorphous and crystalline lump and chip graphite, material that for certain applications cannot be replaced satisfactorily by other forms of natural graphite or by manufactured graphite. Ceylon's reserves, production, foreign trade, and consumption of other mineral and metal commodities were insignificant in terms of world totals. However, the cement industry ranked ahead of the graphite industry in value of output, and thus was of greater local economic importance.

The total value of Ceylon's 1963 mineral output is estimated at about 25.6 million Ceylonese rupees (Cey Rs) (US$5,376,000) or about 0.4 percent of the country's gross national product. Of total mineral industry output value in 1963, cement accounted for about Cey Rs8.6 million, graphite for about Cey Rs5.1 million, gems for approximately Cey Rs3.6 million, and salt for nearly Cey Rs1.9 million.

Ceylon's 1962 mineral and metal imports, with a value of approximately Cey Rs271 million (US$57.0 million), constituted about 16.3 percent of total imports, while mineral and metal exports were valued at about Cey Rs9.25 million (US$1.9 million) and constituted about 0.5 percent of total exports. This situation contributed to an unfavorable trade balance. Of the total value of mineral and metal imports, mineral fuels accounted for nearly half.

The Ceylonese mineral industry provided employment for some 10,000 to 15,000 persons in 1963. This included several thousands working only seasonally for recovery of solar salt and part time for the recovery and cutting of gems. Total mineral employment represented less than 0.5 percent of the nation's labor force.

GOVERNMENT POLICIES AND PROGRAMS

The trend toward government ownership of industry, apparent for several years, continued in 1963. Construction continued on the Government-owned steel-rolling mill being built under an economic-technological aid program with the U.S.S.R. Completion of a Government-owned kaolin refinery and a corresponding expansion of the government-owned ceramics plant were reported.

Increasing penetration of the private sector of the minerals industry was exemplified by the declaration in late 1963 of the government's plans to grant monopolistic status in petroleum product distribution

[1] Physical scientist, Division of International Activities.

Digitized by Google

to the government-owned Ceylon Petroleum Corp., effective January 1, 1964. This declaration was accompanied by a government statement of intent to acquire all remaining facilities of the three private oil companies operating in Ceylon. Previously (1962), the government had acquired part of the distribution facilities of these companies, to provide outlets for the then newly created government company.

Among other established government enterprises, the Ceylon Minerals Sand Corp. showed a gain in output but had not yet attained its production potential, the National Salt Corp. failed to meet its programmed goals, and the Ceylon Cement Corp. fell considerably short of its record production of 1962.

SOURCE MATERIAL

Production data for most commodities were derived from publications of the Government of Ceylon, supplemented (particularly in 1963), in the absence of such sources, by data furnished by the U.S. Embassy in Colombo. Specifically, the Ceylon Yearbook, Administrative Reports of the Government Mineralogist, Administrative Reports of the Salt Commissioner, and Administrative Reports of the Director of Industries should be cited. Foreign trade data were taken entirely from the Ceylon Customs Returns. Published data on output and trade are reliable, but information on production of gem stones and most construction raw materials (clays, crushed stone, dimension stone, and common sand and gravel) are not recorded by the government. The level of gem output may be roughly gaged by the level of gem exports, but no reliable estimates can be made for the construction raw materials. Information on mineral exploration, plant development, and technology is from a wide variety of sources, including the governmental reports previously cited, recent newspaper and magazine articles, and Embassy reports.

PRODUCTION

Output of Ceylon's three most significant industrial mineral commodities—cement, graphite, and salt—declined in 1963, but value of total output apparently was slightly higher than in 1962 because of increases in value of production of ilmenite, gem stones, feldspar, and glass sand. Causes of decline in cement and graphite production were not clear; declining salt production apparently reflected poor salt-harvest climatic conditions, and continued effects of administrative and technological difficulties experienced by the salt industry for several years, which the government apparently had not completely rectified by yearend.

[1] Ceylon also produces chalk and a wide variety of precious and semiprecious gems. Output of chalk is estimated at less than 1,000 tons per year; output of gems somewhat exceeds exports, which totaled 157,538 carats in 1963.
[2] Data not available.
[3] Exports; actual production data not available.
[4] Final figure; differs from estimate reported in commodity chapter in volume I.

TRADE

As in the past, Ceylon's significant 1963 mineral exports were limited to ilmenite concentrates, graphite, and precious and semiprecious gems. Requirements for iron, steel, all nonferrous metals, many nonmetals and all mineral fuels were supplied by imports. The value of mineral imports in 1962 (271 million Ceylonese rupees) was distributed as follows:

Major classes of commodities:	*Percent*
Iron and steel	23.5
Nonferrous base metals	6.0
Precious metals	.7
Nonmetals	9.7
Construction materials	10.3
Coal and coke, including briquets	3.4
Petroleum products	46.4

Over half of the total iron and steel imports in 1962 consisted of structural steel bars, rods, and sheet goods. Aluminum was the principal nonferrous base metal import. Fertilizers accounted for over 80 percent of the total value of nonmetals imports; cement was by far the leading construction material imported.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

COMMODITY REVIEW

METALS

Ilmenite.—Production by the government-owned Ceylon Mineral Sand Corp., from the Pulmoddai deposit on the northeast coast of Ceylon, increased sharply in 1963. Output of the plant, even at the production peak recorded in 1963, was only about one-third of installed capacity. Rated capacity remained unchanged at 60,000 tons of ilmenite per year from a feed of 100,000 tons of sand, with recovery of associated rutile and zircon. Lack of markets reportedly has been the reason behind curtailed production.

Iron Ore and Iron and Steel.—Construction of a rolling mill at Oruwella, which was started in late 1961, continued during 1963. The target completion date remained 1965. The mill has a planned annual capacity of 10,000 tons of wire rods and 25,000 tons of merchant sections, and was being built for the government-owned Ceylon Steel Corp., with technical and financial assistance of the U.S.S.R., at a cost of 80 million Ceylonese rupees (US$17 million). It is the first phase

Digitized by Google

of a small integrated steel industry designed to reduce import requirements, which averaged 67,716 tons per year during 1958–62. Further phases, still in the planning stage at yearend, included the installation of a steel furnace to process imported pig iron and imported or domestic scrap, and subsequent erection of either a blast or an electric furnace to smelt indigenous iron ore.

The country's known iron ore resources in 1963 were estimated to total 8 to 14 million tons of material containing over 50 percent iron. Of this, 4 million tons consists of hydrated iron oxides, chiefly limonite, in a number of scattered deposits in the southwest part of the island. These are regarded as economically marginal. The balance is in an incompletely explored magnetite deposit at Kottikanda-Panirendawa, which reportedly contains 4 to 10 million tons with an iron content of 65 to 70 percent.

Monazite.—Monazite output during 1959–61 was from a small deposit on the southwest coast at Beruwela, and apparently was stopped in 1961 owing to the absence of a market. This deposit was worked by the Ceylonese Department of Mineralogy, operating a small plant with several Exolon magnetic separators. Output consisted of 99 percent monazite concentrate with reported rare-earth oxide content of 66 percent, including thoria. Of 457 metric tons of this material stockpiled at the start of 1963, 305 tons was exported during the year, leaving 152 tons in stock.

Nonferrous Base Metals.—As in previous years, Ceylon's entire nonferrous metal requirement in 1962 was met by imports. Apparent domestic consumption of the various metals, as indicated by average imports during 1958–62, are presented in table 4.

TABLE 4.—Average nonferrous base metal imports during 1958–62

Commodity	Principal forms	Unit	Quantity
Aluminum	Sheet	Metric tons	2,287
Copper and alloys	Copper wire, copper and brass semifinished products.	do	572
Lead	Ingot	do	166
Tin	Ingot and solder	Long tons	[1] 54
Zinc	Ingot	Metric tons	137

Digitized by Google

NONMETALS

Cement.—The government-owned Ceylon Cement Corp. plant at Kankesanturai was the country's only operating cement works. In 1963 the plant produced at about 75 percent of its rated capacity of 100,000 metric tons annually, supplying 25 to 30 percent of Ceylon's apparent requirements. Expansion of this plant to a 250,000-ton-per-year production level, underway in 1963, was scheduled for completion during 1964. Development of ancillary facilities for a 200,000- ton-per-year clinker-grinding plant at Galle continued during 1963. Completion of the plant was scheduled for 1965. A second cement plant was projected for erection at Puttalam.

Graphite.—Ceylon's major graphite mines continued to produce at a level in keeping with demand for Ceylon's special grades—amorphous and crystalline lump and chip graphite. However, output remained far below the levels which were attained before and during World War II, and which apparently could be attained again should demand rise. Total reserves, though not reported, are known to be adequate to support production at considerably higher levels of production for a number of years. About 1,000 small mines have produced when market prices were high; virtually all of these remained closed. The Bogala property apparently produced about half of the output.

Kaolin and Ceramic Materials.—Expansion of the government-owned Negombo ceramics plant from a 500-ton to an 840-ton annual capacity continued in 1963. A contract for the erection of Ceylon's second ceramics plant was awarded to a British firm. Completion of this plant, at Boralesgomuwa, was slated for January 1965. Raw materials are to be provided by another major plant in the overall ceramics industry expansion scheme, a 5,500-ton-per-year kaolin refinery at Boralesgomuwa. This facility, already completed, cost about Cey Rs3.8 million (US$800,000). The government expects that completion of the whole ceramics industry development program will make the nation self-sufficient in crockery.

Salt.—Ceylon's salt output declined to the lowest level recorded since 1958. Diminished production apparently was attributable to poor climatic conditions during salt harvest seasons and continued administrative and technological difficulties of the National Salt Corp., the government-owned corporation established to develop salterns on the island's southeast coast. During 1962, this organization failed to complete development of its saltern complex at Hambantota (underway since 1957) and consequently was unable to meet its 1962 production goal of 300,000 tons of salt, including 200,000 to 250,000 tons for export. A special high-level governmental commission was established to investigate the activities of the salt commission. The report of this commission, cited numerous instances of technological and financial mismanagement within the corporation.[2] This report led to a reappraisal of the goals of the Hambantota scheme, which were revised downward drastically. Under the more realistic scheme adopted, Hambantota was to provide only part of the domestic requirements, supplementing the production from other salterns, notably

[2] Government of Ceylon. Report of the Commission on the Salt Corporation. Sessional Paper 9—1963. Government Publications Bureau, Colombo, July 1963.

Digitized by Google

the traditionally first ranked Elephant Pass facility in the northern part of the island. However, because of the amount of work still necessary to ready the Hambantota area salterns for production as of the end of 1962, the new management was unable to bolster 1963 output levels.

MINERAL FUELS

Petroleum.—In late 1963, the three private firms—Caltex Ceylon, Ltd., Esso Standard Eastern, Inc. (Ceylon), and Shell Co. of Ceylon, Ltd.—that had shared Ceylon's markets with the government corporation through 1962–63 were notified of the government's intention to acquire all their remaining distribution facilities in early 1964. Negotiations with these firms over compensation for facilities acquired by the government in 1962 continued throughout 1963. Government proposals advanced during these negotiations did not comply with the Hickenlooper amendment to the U.S. foreign aid bill; therefore the entire Agency for International Development (AID) technical assistance program for Ceylon was suspended on February 8.

Petroleum products imports from the U.S.S.R., nil in 1960–61, increased to 21 percent of the total in 1962 and were significant in view of the changes in domestic distribution.

The Mineral Industry of Mainland China

By K. P. Wang [1]

MAINLAND CHINA is an important mineral producer by world standards, although not in terms of per capita output. Its estimated 1963 mineral output value (mine output plus added value derived from smelting and processing) of approximately US$3,500 million, although only a little more than half that of Japan, exceeded that of the rest of the Far East countries put together and ranked mainland China just within the first 10 top mineral producing nations in the world. The mining component of the Chinese mineral industry remained much stronger than the metallurgical component; coal alone provided about 40 percent of the total mineral production value in 1963.

Mainland China produces not only most basic minerals needed for its own industrial development but also produces many other minerals primarily for export. Many minerals were extracted in world significant quantities during 1963. In 1963 the country was one of the three foremost world producers of bituminous and anthracite coal; tin, tungsten, and antimony; and salt and magnetite. It also ranked about fifth or better in bismuth, manganese, mercury, molybdenite, asbestos, fluorspar, and graphite; about seventh in iron and steel; and about tenth in the major nonferrous metals, cement, barite, as well as pyrite and sulfur. Notable production deficiencies continued in several commodities including petroleum, chromite, nickel, copper, and phosphate rock; known reserves of most of these were limited.

Mineral products particularly the basic items such as coal, iron and steel, cement, and petroleum continued to be of great importance to the Chinese economy. A firm figure for the 1963 gross national product is not available, but the mineral share may amount to 4 to 6 percent. The mineral industry was responsible, directly or indirectly, for a significant part of the country's expanding industrial production.

The most significant mineral developments in 1963 concerned petroleum. It was claimed near the end of the year that the country had become "mainly self-sufficient" in oil.[2] Apparently this claim was based on the importance assigned to the Ta-ch'ing or Sungliao oilfield in Manchuria. There was news that the fair-sized Maoming oil shale plant in Kwangtung was "basically completed."[3] Negotiations were

TABLE 1.—World significance of selected Chinese minerals in 1963 [1]

Commodity	Approximate rank in world output	Share of estimated world output (percent)	Adequacy in production	Reserves or resources
Metals:				
Aluminum	14	2	Virtually adequate	Considerable.
Antimony	1	27	Large surplus	World's largest.
Bismuth	4	10	do	First rank.
Chromite	Insignificant	Very small	Greatly deficient	Unimportant.
Copper	10	2	Deficient	Moderate.
Gold	Not among the first 20.	Small	Can use more	Do.
Iron ore	4	7	Adequate	First rank.
Iron, pig	5	6	do	Not applicable.
Iron, steel ingot	7	3	do	Do.
Lead	8	4	Slight surplus	Moderate.
Manganese ore	5	7	Surplus	Considerable.
Mercury	4	11	Large surplus	First rank.
Molybdenum	4	4	Sizable surplus	Do.
Nickel	Insignificant	Very small	Greatly deficient	Unimportant.
Tin	2	15	Large surplus	First rank.
Tungsten concentrate	1	38	do	World's largest.
Zinc	11	3	Slight surplus	Moderate.
Nonmetals:				
Asbestos	5	3	Moderate surplus	Considerable.
Barite	10	3	Slight surplus	Do.
Cement	9	2	do	Extensive raw materials.
Fluorspar	4	9	Sizable surplus	Considerable.
Graphite	5	6	Adequate	Moderate.
Gypsum	15	1	do	Considerable.
Magnesite	3	11	Surplus	First rank.
Phosphate rock	8	1	Seriously deficient	Considerable.
Pyrite	5	6	Can use more	Do.
Salt	2	11	Slight surplus	First rank.
Sulfur	9	2	Surplus	Moderate.
Talc	5	5	do	Do.
Mineral fuels:				
Anthracite	2	11	Adequate	First rank.
Bituminous coal	3	14	do	Do.
Coke	6	5	do	Do.
Petroleum, crude	18	.5+	Deficient	Moderate.
Petroleum, refined	Not among the first 20.	.5+	do	Not applicable.

[1] Chinese production estimated by author generally as an order of magnitude rather than as a definitive quantity. Consequently, the determinations of world rank and of share of world output can be regarded only as approximations. Moreover, these determinations may also be inexact because of incomplete or erroneous reporting of the output of other countries.

underway to have the French, Italians, and Japanese help build oil refineries.

In mid-1963,[4] it was reported that about 160 mineral projects were being developed of which more than 60 were in the ferrous and nonferrous fields, including iron, manganese, magnesite, copper, bauxite, tin, and lead-zinc.

In iron and steel, the effort in 1963 was to develop and expand iron mines, improve smelting practices including more widespread use of magnesium-alumina refractories, make best use of available capacities, continue to construct unfinished facilities, diversify and improve the quality of steel products, and build up fabrication facilities. The coal industry was definitely making headway towards increased production during 1963. For the established coal mining enterprises, the program was to extend shafts to greater depths; for coal-short supply areas, the program was to sink new shafts to tap available reserves.

In the fertilizer raw materials field, many pyrite mines and mills and two large phosphate rock mines—one in Hupeh and the other in

[4] Jen-min Jih-pao (People's Daily; Peiping), July 6, 1963, p. 2.

Digitized by Google

Kweichow—were being built. In the cement field, the emphasis was on developing new limestone quarries for existing plants. Work began on doubling the capacity of mainland China's largest asbestos mine in Szechuan during 1963.

GOVERNMENT POLICIES AND PROGRAMS

The first year following the close of mainland China's second 5-year plan was 1963; no announcement of a third 5-year plan was made and thus industrial targets were not revealed.

Stress was placed in 1963 on development of mineral and industrial enterprises. Especially, the policy was to improve product quality, diversify products, reduce cost and increase productivity, and conserve materials and recover more from waste. Accordingly, many mines and plants were consolidated, with the better ones slated for expansion. Small and local operations were not ignored, but their economic indices had to be within a specified range. Investment and basic construction in 1962 had been limited and additional construction in 1963, was primarily devoted to completing half-finished projects. More coal washeries and mineral dressing plants were erected and special attention was given to the development of metal fabrication facilities.

The needs of agriculture were also especially considered in 1963; production of chemical fertilizer raw materials, such as pyrites and phosphates, was expanded. Larger fertilizer imports were reported and arrangements were made to have foreign concerns build fertilizer plants in the country. Even the steel industry, which produced increasing varieties of products in 1963, was geared partly to make steel parts for agricultural equipment.

Mainland China continued to pursue the policy of strengthening the mineral and metal base in support of general economic development. During 1963, emphasis was placed on development of new reserves, a function that had lagged behind exploitation for several years. The policy regarding the disposal of surplus minerals in 1963, when the Soviet Union was no longer the primary purchaser, was to sell to any market.

Impetus was given to training personnel in facilities staffed by Chinese; this was necessary partly because of withdrawal of Soviet technical help. Training of technicians in local schools and mineral enterprises continued to progress. For example, during 1963 the number of technicians, many in on-the-job training, reportedly employed in the Anshan steel enterprise was three-fifths more than were employed 3 years previously. Also, the first cement, oil, and fertilizer plants designed and built by Chinese were placed in operation during 1963. However, the need for advanced technology was recognized and accordingly, the Chinese negotiated contracts to have foreigners build industrial and mineral plants, such as those for oil, fertilizer, and aluminum.

PRODUCTION

Mineral output value of mainland China during 1963 was about 10 percent more than in 1962, reaching an estimated level of roughly

Digitized by Google

US$3.5 billion. This was approximately the same level as in 1959 and was much below the 1960 peak. The mineral industry, with a reasonably good metallurgical sector, operated substantially in a conventional manner during 1963 after having done away with many small inefficient enterprises previously established in haste.

TABLE 2.—Production of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:					
Aluminum:					
Bauxite [2]	300,000	350,000	400,000	400,000	400,000

Coke, do	20,000	25,000	15,000	15,000	15,000
Petroleum:					
Crude, do	[3] 3,700	[3] 5,500	6,200	6,800	7,500
Refined, do	4,000	5,500	5,500	6,500	7,000

[1] Estimated except for a few claimed figures (see footnote 3).
[2] Mostly diasporic bauxite. Data shown include only the bauxite for aluminum manufacture. Actually, 100,000 to 200,000 tons were produced each year for making refractories.
[3] Claimed figures. Coal, pig iron, and steel data appear to be grossly exaggerated by perhaps one-fifth or more.
[4] Converted to equivalent 50 percent Fe ore.
[5] Recoverable metal content of mine production is also estimated at the same level.
[6] About 68 percent WO_3 grade.

Coal accounted for about two-fifths of the 1963 mineral output value; iron and steel (including ferroalloy), just under 35 percent; petroleum, nonferrous metals, and cement, each about 7 to 8 percent; and nonmetallics, chiefly salt, 4 percent. Thus, coal overshadowed petroleum and iron and steel was far more important than nonferrous metals, although quite a few lesser nonferrous metals were outstanding by world standards.

Digitized by Google

The Chinese Communists have not reported any mineral output statistics since 1960 when many figures apparently were grossly exaggerated on account of the confusion of the "Great Leap." Most of the lesser items have never been reported.

Mineral production during 1961 and 1962 apparently was considerably lower than in 1960, particularly for basic products such as coal, iron and steel, and cement. The 1963 estimated output levels for most minerals, although higher than in the previous 2 years, were still much below the reported 1960 peaks. There are important exceptions to these generalizations. Petroleum production apparently has been steadily increasing, with the 1963 output of crude at about twice the 1959 rate. Output of nonferrous metals has been generally stable. Production of fertilizer raw materials increased during this period, and salt output fluctuated with the weather. Production of the asbestos industry increased and was about to be enlarged substantially.

TRADE

The trade volume of mainland China, which was never much of a trading country, declined sharply in recent years as a result of the internal economic dislocation and strained relations with the Soviet Union, mainland China's principal trading partner. Mineral and metal products, however, occupied an important place in overall international commerce, normally accounting for perhaps 15 to 20 percent of both exports and imports. In fact, Chinese mineral exports attained a maximum annual level of approximately US$200 million a few years ago. Generally, production of mainland China's traditionally exported minerals showed no radical decline in 1963; however, export sales were difficult because of unwillingness of the Soviet Union to buy and because the Chinese lack time to establish new channels. Mineral imports were reduced sharply, which was partly caused by somewhat higher domestic output.

Absence of official Chinese statistics makes it difficult to concisely evaluate mineral trade. However, Soviet trade with mainland China covering 1960–62 shows important trends. In this period, Soviet overall exports to mainland China declined from 735 million to 210 million rubles,[5] and mineral exports dropped from about 165 million to 102 million rubles; Soviet overall imports from mainland China declined from 763 million to 465 million rubles and mineral imports dropped from about 130 million to 77 million rubles. Petroleum was by far the most important mineral commodity exported from the U.S.S.R. to mainland China, and shipments probably were much lower in 1963 than in 1962. The bulk of Chinese mineral exports to the U.S.S.R. comprised tin, tungsten, antimony, molybdenum, mercury, bismuth, cement, and miscellaneous nonmetallics.

Chinese trade with Japan, although of historical and potential significance, was small in 1963. Breakdown statistics on mineral imports by Japan from mainland China during 1961–62 are of interest from the viewpoint of items rather than tonnage. Virtually all mineral products shipped from mainland China to Japan consisted of crude materials, whereas shipments from Japan were primarily manu-

[5] 0.9 ruble equals US$1.

Digitized by Google

factured products like iron and steel as well as chemical fertilizers. Chinese iron ore and bituminous coal were exported only in nominal amounts in 1963.

Chinese mineral exports to Eastern Europe and Western Europe in 1963 increased somewhat over those of 1962, a trend that may continue unless trade relations between the U.S.S.R. and mainland China are readjusted. Mainland China occupies a dominant world position in tungsten and antimony; sales of these metals from China in Western European markets during 1963 temporarily depressed prices there. Significant quantities of phosphate rock from North Africa and copper from Chile were imported by mainland China in 1963.

COMMODITY REVIEW

METALS

Iron and Steel.—An upturn for the Chinese steel industry was clearly evident in 1963. Apparently, steel ingot output rose by about 2 million tons compared with that of 1962. This industry had been hit even harder than the coal industry by the debacle of the "Great Leap" and the departure of Soviet technicians. Steel production during 1961 was not much more than half of the exaggerated claim of 18.45 million tons for 1960. Most small operations were abandoned and only a few were earmarked for future expansion. Basic construction came to a standstill, with many plants only one-half finished. Even as late as 1963, much crated machinery for steel plants was awaiting installation; for example a strip mill at the Wuhan Steel Works remained only two-thirds completed. However, the available annual steel capacity of mainland China already was in excess of 15 million tons.

Iron ore extraction and beneficiation received much attention during 1963. Within the Anshan complex, two open pits including Ta-ku-shan were expanded and a new vertical shaft was built for mining high-grade ore. Overburden removal on a new opencut operation progressed at a rapid rate at the Penhsi (Pen-ch'i) Works in Liaoning. A large beneficiation plant of more than 5 million tons of mine-run ore per annum was being built for the Maanshan Works in Anhwei. The Hsiang-pi-shan open pit near Tayeh was enlarged to meet the needs of the Wuhan complex.

Digitized by Google

Emphasis was placed on quality improvement and on raising operational efficiency in general. The Chinese claim that productivity in iron ore extraction was raised one-fourth during the first 8 months of 1963, as compared with 1962 figures. A more meaningful claim was the 8.6-percent drop from 1962 level of coke consumed per ton of pig iron by the key enterprises. The average coke ratio for these enterprises was reported at 610 kilograms for August 1963.

The iron and steel industry of mainland China was concentrated in eight major centers which in 1963 apparently produced about 60 percent of the pig iron and over 80 percent of the crude steel. The foremost of these centers was Anshan. Many other individual plants at various points around the country were primarily important for pig iron production.

TABLE 6.—Mainland China: Estimated pig iron and crude steel output, by major centers [1]

(Thousand metric tons)

Center	1962		1963	
	Pig iron	Steel ingot	Pig iron	Steel ingot
Anshan	4,500	4,500	5,000	5,000
Wuhan	1,200	1,000	1,500	1,400

Total	8,400	8,800	9,750	10,800
Other [3]	6,600	1,200	7,250	1,200
Grand total	15,000	10,000	17,000	12,000

[1] Rolled steel output of mainland China was about 9 million metric tons in 1962 and 10 million tons in 1963.
[2] New steel converters were to have been constructed in mid-1960, but no confirmation of their existence is available. Apparently, surplus Shihchingsham pig iron is sent mainly to Tientsin for conversion to steel and to Tangshan for rolling.
[3] Includes many smaller plants like Penhsi, Tayeh, Lungyen, Hantan, Maanshan, Shihlu (Hainan), Hofei, Sanchiang and Weiyuan in Szechuan, Kunming, Chengtu, and Dairen, etc. Large quantities of pig iron are produced by plants other than those listed as centers, but a large portion of the pig iron was never converted into steel.

At Anshan, approximately 4.5 million tons of steel products, including many types of new rolled products, were produced during 1963. Anshan with nearly 50 mines, mills, and plants and about 200,000 workers is one of the 10 largest steel complexes in the world and has been the training ground for mainland China's steel technicians. The number of technical personnel employed in 1963 was said to be 60 percent more than in 1960. The Chinese claim that by December 15 Anshan had overfulfilled its 1963 targets by 102,000 tons of steel products and 83,000 tons of steel ingots. The 1,513-cubic-meter No. 10 blast furnace underwent major repairs; nevertheless it reportedly achieved its output goal for 1963. Anshan's 10 blast furnaces and 25 open-hearth furnaces were capable of producing more than 16,000 tons of pig iron and 18,000 tons of steel ingot daily. With new magnesium-alumina refractories, the No. 17 open-hearth furnace established a record of 700 heats of continuous operation in 332 days.

Digitized by Google

At the end of 1963, the 3-million-ton new steel center at Wuhan was about two-thirds completed and was operating at half its ultimate capacity. Installed facilities included a sintering plant, two blast furnaces (1,386 and 1,436 cubic meters), five open-hearth furnaces (one 250-ton and four 500-ton capacity), byproduct coke ovens, a 1.5 to 2-million-ton blooming mill, and a rolling mill. The Chinese Communists claim that Wuhan's 1963 outputs of steel and rolled steel were nearly 50 percent greater than in 1962.

The Paotou steel center, also planned for a 3-million-ton production, was only one-third to one-half completed as of 1963. A 1,513-cubic-meter blast furnace (first of three) and a 600-ton open-hearth furnace had been readied for operations back in 1960, and construction had begun on a second blast furnace, on two more large open-hearth furnaces, and on many other facilities necessary for integrated iron and steel production. The Chinese Communists reported that Paotou's pig iron and steel outputs in 1963 were respectively 11 and 100 percent greater than in 1962. It appears therefore that one blast furnace and one open-hearth furnace were being operated in 1962 and that an additional second open-hearth furnace was also in use in 1963.

Shihchingshan, with three blast furnaces (the largest is a 1,000-cubic-meter blast furnace which has a capacity greater than the other two combined), had a total pig iron capacity of about 1 million tons. Other facilities operating in 1963 include sintering plant, byproduct ovens, converters, and rolling mills for bars, plates, and pipes. Steel and rolled steel capacities were much smaller than pig iron production and surplus pig iron went mainly to the Tientsin plant for conversion into steel and thence to the Tangshan plant for rolling. These three plants put together should be looked upon as being integrated and capable of producing 1 million tons plus of steel products per annum.

Shanghai has at least 10 medium or small iron and steel plants of various kinds, which together can produce about half a million tons of pig iron and 2 to 3 millions tons of steel annually. The steel furnaces are mostly Bessemer converters. The Shanghai No. 1 Steelworks alone, with the bulk of the metropolitan area's pig iron capacity (two blast furnaces), reportedly produced half a million tons of steel products in 1963. At yearend, a small tin-plating mill was readied for operations at the Shanghai No. 10 Steelworks.

Taiyuan has several blast furnaces, including one of 1,000 tons per day, plus byproduct coke ovens and corresponding steel and rolling facilities. Output is conservatively estimated at about half a million tons of steel products in 1963.

The Chinese press frequently mentioned Chungking as an important steel plant in 1963. As a minimum, this plant had a 620-cubic-meter blast furnace, a 300,000-ton-per-annum byproduct coke unit, refractory facilities, four open-hearth furnaces, and rolling mills to produce plate, rail, pipe, and seamless tube. An equivalent-size pig iron and steel capacity was reportedly under construction in 1960. The Chinese claim that pig iron output in the first 9 months of 1963 was 105 percent of the 1962 total. It is conservatively estimated that pig iron and steel outputs for Chungking in 1963 were both abtout 400,000 tons.

Other Metals.—The Chinese Communists seldom discuss their "colored" metals industries; however, indirect information on trade and

Digitized by Google

developments in nonferrous metals and ores are occasionally available so that rough output levels for many items can be estimated. Generally, Chinese nonferrous metals had a reasonably good year in 1963. Established mines and plants were not seriously affected by the previous economic dislocations. Basic construction on new projects and expanded capacity picked up after several years in the doldrums. Some surplus minerals were bartered for deficient ones, and hard currency and precious metals were used sparingly to buy items in critical short supply. Regarding the famous "export" metals, reduced trade with the Soviet Union forced mainland China to seek markets elsewhere and thus caused disturbances in freeworld metal supplies and prices.

Mainland China produced about 7 percent of the world's manganese ore in 1963, but half was low-grade and high in iron. An offer of 20,000 tons of manganese ore to Japan for 250 tons of chromium metal was made. Shortages in metallurgical and refractory chromite were not alleviated, and the Soviet Union stopped shipments in 1961–62. The Chinese claim success, however, in using magnesia-alumina brick in lining steel furnaces as a substitute for refractory chromite. The nickel shortage was also severe, and imports came from Cuba which reportedly furnished 5,000 tons of contained nickel in oxides and sulfides during 1962. The Chinese steel industry although consuming most of the manganese ore, uses very little tungsten and molybdenum.

Of the nonferrous base metals and light metals, only copper was in short supply. During 1963, the Chinese bought 10,000 tons of Chilean copper for about US$8 million cash payment to supplement indigenous production about ten times this amount. Zinc production appeared sufficient for domestic needs, and there was a little surplus of lead. The heart of the Chinese aluminum industry was still the Fushun plant in Manchuria. Bauxite was produced not only for aluminum manufacture but also for refractory use in steel furnaces.

Mainland China's famous export metals; namely, tin, tungsten, antimony, mercury, bismuth, and molybdenum, had a somewhat difficult year in 1963 not because of production but because of marketing difficulties. Tin output was still slightly lower than the historic peak of 30,000 long tons, with Kuchiu holding its own and Kwangsi having some operational problems. The trend towards greater tin exports to the free world and Eastern Europe and reduced shipments to the Soviet Union continued. In 1963, the U.S.S.R. imported only 4,300 long tons of Chinese tin, or about half of the 1962 tonnage. Tungsten production held firm at about 20,000 metric tons of concentrates, with most surplus still going to the Soviet Union (12,000 tons in 1963). During 1963, the Chinese first flooded Western Europe with tungsten and then withdrew in the last quarter of the year when prices became very low. Chinese antimony also disappeared from Western markets. Exports of mercury increased; sizable quantities went to the Soviet Union and Eastern Europe in 1962–63 and to the United Kingdom in 1962. The annual surplus in molybdenum remained at perhaps 1,000 tons contained in concentrate and ferromolybdenum. Large molybdenum deposits were still being developed.

Digitized by Google

NONMETALS

Asbestos.—Production of asbestos was used in cement and textile products and also was exported. Output in 1963 rose by about 10 percent over that of 1962. Thus, mainland China maintained growth in this relatively new industry uneffected by the depressed economy in recent years and more than retained its position as a medium world producer of good quality, long and short fiber asbestos. The Shihmien area in Szechuan, with about a dozen mines supplying a large ore dressing plant, was the source of more than two-thirds of the country's asbestos; the area embarked upon an expansion program to double 1962 output.[6] Ten projects aimed at greater mechanization and higher output were started during 1963. These included a large hydroplant, electricity transmission stations, an access highway, storage and vehicle maintenance facilities, compressed air stations, and four additional mine adits. Four of these projects were completed by October, enabling output for the first 8 months to increase by 12 percent over that of the same period in 1962.

Cement.—Output of cement in 1963 was nearly 2 million tons higher than during 1962. The Chinese claim [7] that the 1963 cement target for large and medium plants was achieved on November 10 and that combined output for these plants during the first 10 months was 24 percent higher than in the same period of 1962. The relative production increase for small plants, which contributed roughly 15 percent of the country's cement, was lower than for the large and medium plants. Generally, the industry became more stabilized in 1963, with operational standards and product quality much improved as compared with the "Great Leap" years. Demand for cement rose considerably in 1963 and exports, mainly to the Soviet Far East from Manchuria, remained at the level of 0.5 to 0.9 million tons yearly. Whereas some areas, including Manchuria, had cement surpluses; others, such as northern China, had shortages. The overall cement raw material position remained good, although many plants had to develop more reserves.

About a third of the approximately 50 large and medium cement plants (with 90 to 100 kilns, mostly rotary but some vertical) were mentioned in the Chinese press. For example, Liuliho by achieving the year's output goal 39 days ahead of schedule was able to produce more than 60,000 tons over the target. Chungking, after raising 1962 output 25 percent above the 1961 level, made another 3.5 percent improvement in the first 10 months of 1963 despite the usual wet summer weather which hindered operations. Ch'ihsin fulfilled its 1963 goal about November 12. Kwangchow brought its fourth kiln (125 meters long and 3 meters in diameter), the first modern, rotary, Chinese-designed and Chinese-built cement kiln, into operation during May. Yungteng, which surpassed its 1962 target by 30 percent, further raised output in 1963. Tzupo's first stage 160,000-ton plant started production in August. The Liuchow plant, built with Czech help, was nearing completion late in the year. The Chungkuo plant in Nanking ran its No. 3 kiln nearly a year without stoppage. Kiangnan was said to be the

Grand total		14,000	10,000

[1] At least 20 other so-called large and medium plants have been mentioned in literature as being partly or wholly constructed, including two important ones; namely, Hantan in Hopeh and Hsiao-t'un in Liaoning. Estimated combined output of these and numerous very small operations is given under "Other."

only plant making oil well cement. By making technical improvements, hourly output of Mutanchiang was raised from 29.4 to 38 tons.

Many mines and quarries were being developed or expanded for the cement industry. For example, the K'ungshan limestone mine was being reconstructed and enlarged to meet the future needs of the Chungkuo and Kiangnam cement plants. The Huangchinshan limestone quarry was being developed for the Huahsin cement plant. A new limestone quarry was also being opened for the Ch'ihsin plant in Tangshan. Development of the Luchuang sandstone mine near Chingwangtao was reportedly nearing completion. The Fushun cement plant in Manchuria continued to use byproduct oil shale as a raw material. Most established cement plants strengthened their raw material base during 1963. Gypsum has never been a problem, indigneous mines provided the 300,000 to 400,000 tons consumed in cement manufacture in 1963.

Fertilizer and Chemical Materials.—Mainland China's problem with food shortages dictated the policy of developing new sources of fertilizer and chemical raw materials. Special emphasis was given to pyrite and phosphate.[8] It was claimed that, for making ammonium sulfate

[8] Jen-min Jih-pao (People's Daily; Peiping), July 6, 1963, p. 2.

Digitized by Google

alone, 14 new pyrite mines were being developed in mid–1963. A new benefication plant for producing pyrite concentrates containing 35 to 40 percent sulfur was placed in operation at the Hsiangshan mine in Anhwei Province late in the year. This plant is of strictly Chinese design and became the largest in the country; its initial annual capacity was rated at 400,000 tons of ore. The Yingte mine in Kwangtung Province, with an eventual yearly capacity of 300,000 tons of pyrite, was claimed to be nearly one-half completed. Seven small mines in Kwangtung Province were being expanded to a combined yearly pyrite output of 120,000-odd tons. Many other pyrite mines were in operation, and nonferrous mines provided several hundred thousand tons of pyrite in 1963. Numerous small mines in Szechuan and Shansi also produced pyrite for sulfur.

Demand for phosphate rock continued to rise, and the policy was to increase domestic production so as to replace imports, such as the approximately 270,000 tons from Morocco in 1963. Accordingly, several large mines were in various stages of development. The 600,000-ton-per-year (first stage capacity) Chinghsiang phosphate rock mine in Hupeh Province, of Chinese design and well mechanized, was virtually completed at yearend. A second large phosphate rock mine was under development at K'aiyang in Kweichow Province. A modern phosphate fertilizer plant in Nanking had been in full-scale operation for several years. Another phosphate plant, rated at 300,000-odd-tons-per-year capacity, in Ch'angsha, Hunan Province, is expected to start production in 1964. Greater output of pyrite and sulfuric acid to meet the needs of phosphates and other chemical fertilizers became more pressing toward the end of 1963.

A considerable increase in chemical fertilizer production was claimed for 1963, however, the apparent available supply of 4 to 5 million tons, two-fifths imported, was far short of demand. Seven major nitrogenous fertilizer projects in various parts of the country were reported to be in various stages of construction with some nearing completion by the end of 1963. The Wuching plant in Shanghai, the first to be designed by the Chinese and rated at 25,000 tons of urea or 100,000 tons of ammonium sulfate, went into production late in the year. At a plant near Canton (Kwangchow), ammonium sulfate production started early in April. A byproduct ammonium sulfate plant was also completed at the Chungking Iron and Steelworks.

The Chinese were active in purchasing foreign fertilizer plants. A US$8.4 million ammonia plant was ordered from Humphreys and Glasgow, Ltd., of the United Kingdom for Luchow in central China. Subsequently, a complementary $7 million urea fertilizer plant for Luchow was ordered from Continental Engineering of the Netherlands. Negotiations with a West German fertilizer firm in 1963 apparently did not result in a contract. However, the Italians may be asked to build two large ammonium sulfate plants.

Although pyrite is the main sulfur-bearing raw material used in making sulfuric acid and fertilizers in mainland China, elemental sulfur is of equal importance. During 1963, about half of the roughly 250,000 tons of sulfur produced came from pyrite and the other half came from 20-percent sulfur ores. The country had surplus sulfur

Digitized by Google

but the tonnage exported, mainly to the Soviet Union, has been declining in recent years.

Salt.—Mainland China retained its position as the world's second largest producer of salt in 1963, with output of about 10.5 million metric tons, 6 percent more than in 1962. Most of the salt was consumed for food purposes, but a plentiful supply is available for making chemicals. The bulk was produced from the coastal provinces by evaporation of sea water, the largest fields being Ch'anglu in Hopeh and Ying-kai in Liaoning. Efforts were made to improve the quality of crude salt and streamline the salt farms which basically are greatly dependent upon the weather. Salt farms in coastal Kwangtung reportedly had a very good year in 1963. The Tzuliuching salt wells near the oil and gasfields in inland Szechuan Province, which provided about one-tenth of the national salt output, reportedly improved the efficiency of drilling operations and evaporation during 1963.

Other Nonmetals.—Magnesite from Manchuria was still of great world significance, but output in 1963, although greater than in 1962, had not yet returned to the peak level of a few years ago. The Anshan enterprise opened a new magnesite facility in 1963, and consumption of this material in making refractories became much more widespread. A surplus of barite was apparent despite increased needs in oil drilling. Fluorspar production from Chekiang and north China remained steady to meet the combined needs of steel, aluminum, and exports. One-half of the Chinese steatite talc from Taling, Liaoning was used in the domestic market and the other half in foreign markets. In recent years, polished marble slabs have been exported.

MINERAL FUELS

Coal.—The Chinese coal industry received much emphasis during 1963. Of the 160-odd major mining projects reportedly undertaken during the year, a large number were coal projects. The Chinese Communists claim that 67 pairs of new coal shafts were under construction at the end of 1963, mostly in the low-level coal production areas of eastern, central-south, and northwest China. Thus, 30 to 40 million tons of annual coal capacity was being developed, assuming that each pair of shafts ranges from 200,000 to 1 million tons and that the average is 500,000 tons. In addition, 60-odd pairs of shafts reportedly were being extended at the established coal mining centers, another aspect of expanded future capacity.

Coal production improved in 1963 and output was about 20 million tons higher than in 1962. Thirty-three coal mining administrations with at least 66 key mining projects provided about two-thirds of the country's coal in 1963. The seven big coal mines (Fushun, Fushin, Kailan, Huainan, Chihsi, Hokang, and Tatung, roughly in descending order) each produced 10 to 20 million tons and together approximately 100 million tons. Half a dozen others were in the 5- to 9-million-ton range, still another half dozen were in the 2- to 5-million-ton range, and the remaining mines were in the 1- to 2-million-ton range each. The total from the 33 administrations was roughly 180 million tons. Adding about 90 million tons for the medium and small mines, many

Digitized by Google

having daily capacities of 500 to 2,000 tons, mainland China's overall 1963 coal output is estimated at 270 million tons. The bulk was bituminous coal, with anthracite only some 20 million tons. Possibly 20 million tons were produced by hydraulic mining during 1963.

Fluctuations in coal output during recent years were not as great as figures imply. The claimed 1959–60 data probably were exaggerated by about 20 percent on account of unrealistic claims and inclusion of very dirty coal so that the 1960 production, for example, may have been only some 350 million tons on a basis comparable with 1963. A precipitous drop occurred in 1961 as an aftermath of the "Great Leap" disaster, forcing closure of many inefficient small mines and dislocating normal operations of large mines. Coal demand was sharply curtailed and many operations were not able to produce at former levels because of depletion of blocked out reserves. In 1962, the small mines surviving the crisis were consolidated and enlarged, and operations of the established mines were normalized. The trend continued in 1963, while coal facilities in areas of lesser reserves were being constructed.

About 5 to 10 million tons of new coal capacity was created in 1963, and much development in facilitating production and delineating reserves was done. The Chinese Communists claim [9] an increased productivity of 18 tons per man-year over that of 1962 and reductions of 4.5 percent in cost and of 25.5 cubic meters of mine timber consumption per 10,000 tons of coal output, as compared with the previous year. Coal beneficiation and quality control were stressed, resulting in an average drop of 1.5 percent in ash content of ordinary coals and of 0.8 percent in ash content of coking coals. Definite contract arrangements were made between coal producers and major consuming industries to stabilize marketing.

Petroleum.—Mainland China's oil production, unlike that of other industrial products, was not seriously affected by the economic collapse. Exploration in some fields and refinery construction were slowed down for a few years, but overall output continued to rise steadily. In 1963, production of crude oil (including oil from shale) was approximately 7.5 million tons or twice the 1959 level; virtually all crude oil was domestically refined. Furthermore, imports (bulk from the U.S.S.R. and some from Rumania) declined from about 3 million tons in 1961 to 2 million tons in 1962 and to possibly 1.4 million tons in 1963, primarily because of the Sino-Soviet impasse and the Soviet decision to send lesser amounts to mainland China. The Chinese, in striving for self-sufficiency, developed additional capacity in some fields and discovered a few important new fields. Apparently, a 10-million-ton-per-year industry is in sight.

Chinese claims of accomplishments during 1963 include fulfillment of the year's production goals for crude oil and refined petroleum; near self-sufficiency in terms of both quality and type of basic oil products like gasoline, kerosine, diesel oil, and lubricants; an output increase of crude oil of roughly 11 percent over that of 1962; 18 to 35 percent rise in byproducts, including ammonium sulfate, carbon black, paraffin, and tar; completion of new refining capacity 4 to 5 times that built in 1962; a 70-percent increase in capital construction of oil fields

[9] Ta-kung Pao (Peiping), Dec. 31, 1963, p. 2.

Digitized by Google

during the first two-thirds of 1963, as compared with same period in 1962; and a capability in manufacturing most basic equipment needed in oil prospecting, drilling, pumping and refining.

The Fushun shale oil enterprise in Manchuria continued to furnish about 1.8 million tons of refined petroleum annually. During 1963 reconstruction of the low-pressure recovery system (which follows retorting) at Fushun resulted in greater processing capacity and higher recovery of light products; also an additional large refining facility was built.

The country's only important natural gasfields are located in Szechuan. The Chinese reported that the 1963 output rate was 16 times that of 1957 and that gas was being piped to industries such as brine salt, electric power, transport, smelting, and chemical. A long distance gasline was completed to a large steel enterprise, presumably Chungking.

Fifteen projects were simultaneously under construction at Sinkiang's Karamai oilfields during 1963, and 38 new oil wells reportedly were brought into production between January and August. The Yumen oilfields showed no great change from previous years. A new important oilfield has been developed in recent years, namely the Sunglioa [10] (Anta or Ta-ch'ing) field between Harbin and Tsitsihar with about 40,000 workers. A second oilfield in Manchuria reportedly has been discovered west of Chinchow (the site of the country's only operating synthetic oil-from-coal plant), but this lacks confirmation. An estimated breakdown of the 1963 crude oil output by fields is as follows, in millions of metric tons: Fushun (shale oil), 1.8; Yumen, 1.8; Karamai, 1.5; Sungliao, 1:5; Szechuan, 0.4; Tsaidam, 0.4; and other 0.1.

The Lanchow refinery, originally designed for 1 million tons, was expanded substantially in 1962–63 both in capacity and variety of products. Among other facilities at Lanchow, a pressure-reduction tower was being installed late in the year. Completion of a big refinery of Chinese design at an unspecified location was claimed for 1963. This may be the new refinery at Fushun, conceivably built to handle some of the crude oil from the Sungliao field. The Shanghai refinery placed a new heavy oil facility in operation. The refinery at Karamai was expanded in 1963, but there was no news of the Tushantzu refinery in the Sinkiang complex. The Yumen refinery in Kansu and the Nanchung refinery in Szechuan carried on uneventfully. There has been no recent information on a large refinery formerly reported under construction at Nanking and the facility may not have been completed. Several modern refineries were reportedly under construction in mid-1963. An estimate and breakdown of the 1963 refined petroleum output is as follows in millions of metric tons: Fushun (shale oil), 1.8; Lanchow, 1.3; Shanghai, 1.0; Karamai and Tushantzu, 1.0; Yumen, 0.4; Tsaidam, 0.4; Nanchung, 0.3; and unaccounted, 0.8.

The Chinese Communists were very active in international oil negotiations in 1963. Inquiries on purchasing foreign crude oil were halfhearted since there seemed to be no immediate need. Offers to sell crude to Japan, presumably based upon the claimed oil discovery

[10] U.S. Consulate, Hong Kong. State Department Airgram A–803, Mar. 27, 1964.

Digitized by Google

near Chinchow, appeared to be temporary in nature in view of the general shortage of oil on mainland China. Arrangements to buy French-controlled Iranian refined petroleum seemed plausible to fill the void left by reduced Soviet shipments, yet the Chinese were stated to have become essentially free from the dependence on foreign oils. The possibility of having the French install a large refinery was investigated, and Chinese technicians visited the Lacq chemical and gas complex in France. An agreement was made with the Italians to build a medium-sized refinery with catalytic reforming and aromatic extraction facilities. Negotiations were underway to purchase US$5.6 to US$8.4 million worth of refining equipment from Japan. The Chinese were clearly interested in special oil refining equipment and facilities from abroad plus international petroleum know-how to supplement their own capabilities.

The Mineral Industry of Hong Kong

By J. M. West [1]

HONG KONG and its new territories, with a combined area of less than 400 square miles and population estimated at 3.6 million in 1963, was a fair consumer of mineral products, although producing only about US$15 to US$20 million in mineral value annually. Operating as a free port, it had one of the world's busiest harbors. Agriculture and fishing were secondary to tourism and trade, which created a great deal of activity in construction and manufacturing. Hotels and reservoir projects to overcome water shortages required large expenditures on construction. Electric power consumption, about 1,530 million kilowatt-hours in 1962, has increased about 20 percent annually. Refugees from the Chinese mainland provided a labor surplus. A cement plant, a number of small metal-processing plants, ship-scrapping facilities, and an iron mine were the main components of the mineral industry. During the year, two steel-pipe plants were under construction, Fuji Marden was expanding its line of steel products, the Ma An Shan iron mine completed a new haulageway to raise capacity, and another oil-bunkering terminal for ships was opened.

GOVERNMENT POLICIES AND PROGRAMS

Although Hong Kong did not have many minerals and only a small mineral-processing industry, the Government was trying to encourage development by an open investment policy and active efforts to stimulate trade. As a free port, Hong Kong enjoyed an unrestricted flow of mineral commodities, part of which was entrepôt trade destined for transshipment. A small mines department was maintained, chiefly for controlling blasting and arranging royalty collections from mineowners. The department granted mining licenses and leases, investigated mine accidents, and published a review of activities.[2] Many of the colony's metalworking industries were Japanese subsidiaries or joint Japanese-Hong Kong enterprises. Nonresident Chinese were also important investors. Government programs to expand water supply facilities, public housing, and other construction required large quantities of cement, steel, and other building materials. Mineral trade was favored by Hong Kong's lack of politically imposed restrictions, preferential treatment as a British Commonwealth member, and eligibility (established in 1962) as a source of purchases financed by the U.S. Agency for International Development.

PRODUCTION

The colony produced a variety of minerals, with cement and iron ore the main products and a less important production of clays, feldspar, graphite, quartz, and wolframite. In previous years there also had been some lead-silver mining. Salvage of metal scrap was a sizable business. Cement output in 1963 was valued at US$3.5 million and iron ore at US$875,500. The per-ton value of graphite ranged from US$24 for the best grade to US$5 for a poorer grade. Iron and steel from scrap contributed about two-thirds of the total mineral output value.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963

[1] Between ½ and ⅔ consumed by the producer in making town gas.
[2] Estimate.

TRADE

Mainland China, recognized by the Hong Kong Government supplied large quantities of coal, cement, and steel products to the colony. Fertilizers were imported from Western Europe and reexported in about the same quantities to mainland China, with 1963 imports nearly tripling the 1962 level. Sizable gold imports were almost all reexported to the gambling city of Macao. Manufacture of surgical-scientific equipment and jewelry accounted for fairly large purchases of foreign platinum, silver, and mercury. Diamond trade was impressive, with total imports valued at US$52 million in 1963. Most of the diamond came from Belgium and Israel. In 1963, about US$370,000 of uncut jade was imported from Burma and US$620,000 of cut and polished but unset jade was imported from mainland China and the Malaya portion of Malaysia. Pearls valued at US$2.8 million came into Hong Kong during the year, nearly all from Japan. Most important among Hong Kong's exports were iron ore, all going to Japan, and steel scrap from shipbreaking, which went mainly to Japan.

COMMODITY REVIEW

METALS

Iron Ore.—Ma An Shan in the new territories, Hong Kong's only iron mine, employed about 650 workers in 1963. Mining from this contact metamorphic deposit was started from the surface but had gone underground. The ores were being magnetically upgraded from 32 to 56 percent iron in an 800-ore-ton-per-day wet concentrator. About one-fifth of the production came from handsorted dump recoveries. Technical assistance was provided by the Japanese, and all production was exported to Japan. Output was expected to double after opening a mile-long tunnel in October 1963, extending to the orebody bottom.

Iron and Steel.—Hong Kong's numerous small iron and steel plants, rolling mills, and foundries produced a limited range of products such as bars, rounds, and flats. The industry employed an estimated 2,700 persons and produced roughly 200,000 tons of steel bars in 1963, working at about two-thirds capacity.[3] Steel-bar consumption was much higher than production, requiring net imports of 149,000 tons. In addition, net imports of other iron and steel products amounted to more than 200,000 tons. Fuji Marden, built in 1960 by Fuji Iron Works (Japan) and Wheelock Marden (Hong Kong) and probably the colony's largest plant, produced about 25,000 tons per years of iron bars and was expanding to include iron sheets, pipe, and galvanized products. The company also was completing a large shipbreaking yard, with the scrap scheduled to be sent to the local mill and, to a lesser extent, Japan. Sigma Shipping operated a rerolling mill on Tsing Yi Island. Sakai Steel Pipe, organized by Japanese and Hong Kong interests, was building a 300- to 500-ton-per-month plant at Kowloon to make pipe from Japanese imported steelplates. Another pipe plant under construction was to produce 2,000 tons per month. It was reported that a stainless steel plant capable of producing 20,000 tons per year of finished products would be built on Lantao Island to utilize the scrap formerly sold to Japan.

Scrap was basic to the local steel industry. Hong Kong, with its busy shipbreaking yards, was a net exporter of 96,000 tons of scrap in 1963. Exports, going chiefly to Japan, were one-fourth higher than in 1962. However, the number of ships imported for breaking fell to 29 from 46 in 1962 because of greater cargo traffic and better freight rates. Fewer ships for scrapping pushed hull prices up. Strips cut from ship plates were rolled directly into steel bars. Remelting, an expensive step with high-cost Hong Kong electricity, was thus avoided and gave producers a small competitive edge over imports, at least for the smaller bars. Larger bars were manufactured by a few companies having electric furnaces.

NONMETALS

Cement.—Apparent consumption of cement, an indication of construction activity, was about 1 million tons in 1963, more than one-third higher than in 1962. Production, all by Green Island Cement Co., Ltd., was slightly above that of 1962, while imports jumped 246,000 tons in 1963. All coal and gypsum and some limestone were imported for making cement. Plans were announced to build a 120,000-ton-per-year clinker-grinding plant in the Hong Kong harbor area; the clinker would be supplied by the Taiwan Cement Corp. in Taiwan, a principal investor in the enterprise.

Other Nonmetals.—Brick and tile clays were mined and processed at brickworks in the Castle Peak area, but production data were unavailable. High-grade kaolin was mined at Cha Kwo Ling, near Devils Peak, by Hong Kong Clays and Kaolin Co., Ltd., and exported mostly to Japan. Graphite from the West Brothers Island deposit, where an interbed 1 to 10 feet thick occurs in sandstone, consisted of two grades, 50- and 80-percent fixed carbon. In 1963, 537 tons of the total production was high grade and a fifth of this was exported to the United States.

MINERAL FUELS

Coal.—The principal coal users were the Hong Kong and China Gas Co., Ltd., the sole producer of coke, and several shipbuilding and ship-breaking yards. Coke was consumed by local foundries. Coal imports in 1963 came mostly from mainland China. Coke had come from that source until 1962 when, because of quality considerations, Chinese coke was displaced by Taiwanese and Japanese coke on the Hong Kong market. Consumption of coal fell one-eighth from 1962 to 1963. Oil, less demanding of precious storage space, was replacing coal. Another factor was a Government prohibition on installing coal-burning equipment in new buildings.

Petroleum.—All petroleum requirements were met by imports of refined products, mainly from Malaysia and the Middle East. Total oil imports in 1963 exceeded 3 million barrels. Small quantities of the oil went to Macao by reexport. Ship and aircraft bunkers were large consumers. Bunkering facilities were expanded when Gulf Oil Terminal, Inc., a Gulf Oil Corp. subsidiary, opened a US$2.5 million harbor terminal at Tsuen Wan in January 1963. Other companies in the harbor area with ship-fueling facilities included Shell Co. of Hong Kong, Standard Vacuum Oil Co., and Caltex (Asia), Ltd.

The Mineral Industry of India

By L. Nahai [1]

IN 1963 India's mining industry accounted for about 19 percent of the world mica output and 7.4 percent of the world manganese output. The country produced 4.8 percent of the world salt output, and for iron ore, pig iron, coal, cement, bauxite, and gypsum, the country's share of total production was from 2 to 2.6 percent. Steel ingot production was 1.5 percent of the world total.

India contributed significantly to other nations' requirements for iron ore, manganese ore, ilmenite, mica, and rare earth compounds. However, exports of manganese ore and ilmenite have declined in the last decade. With respect to export earnings, these declines have been balanced in part by increase in iron ore exports. Other minerals exported during 1963 were bauxite, chromite, magnesite, salt, barite, kyanite, sillimanite, and steatite; but the quantities involved were not very large. Resources of monazite, zircon, and beryl are sufficient to permit their export but normal exports of these minerals are prohibited by the Government. The coal, iron, and steel complex was of the greatest importance to the domestic economy.

The total value of ores and crude minerals produced in India in 1963, exclusive of petroleum and atomic energy minerals, is estimated at US$445 million, or 1.6 percent of the gross national product (GNP) and US$50 million more than in 1962. Coal and lignite accounted for 74 percent of total value, metallic minerals for 12 percent, and nonmetallic minerals for 14 percent. Metals recovered from domestically produced ores and fuels and fluxes had a total value of US$680 million, 18 percent higher than in 1962 primarily because of increased steel production. Iron and steel including ferroalloys accounted for over 91 percent of the metals total; aluminum, antimony (from imported ore), copper, lead, gold, and silver accounted for most of the balance. Cement output, estimated on the basis of US$15-per-ton ex-works, was valued at US$140 million.

In 1962 the average daily number of persons working in and about mines regulated by the Mines Act, 1952, was about 691,000, of which 433,000 were engaged in coal, 26,100 in mica, 50,100 in iron, 39,100 in manganese, and 54,500 in limestone mining. Including the nearly 200,000 employed in steel plants (including rerolling), other metallurgical plants, and cement plants, the total employment in the mineral industry may approach 1 million or about 5 percent of industrial labor.

The most significant mineral industry development during 1963 was that there was no shortage of coal; on the contrary, supply exceeded

---

[1] Near East-South Asia specialist, Division of International Activities.

Digitized by Google

demand. This resulted partly from improved transportation of coal from mines, excessive production of inferior grades which had limited demand, and the failure of other industrial activity to achieve levels anticipated by the third 5-year plan. To improve mineral export potential, mechanical loading facilities were under construction at Visakhapatnam for iron ore exports and port improvements were being made at Madras and Paradip.

The 1956 industrial policy statement remained the basic mineral policy of the Government. Under this statement, most mineral industries are within a category of industries whose future development is an exclusive responsibility of the State. The statement does not preclude the expansion of existing privately owned units or the possibility of the State securing the cooperation of private enterprise in establishing new units. The policy was applied pragmatically in 1963; the Government looked with favor on projects for expanding aluminum output by private industry and licensed expansion of privately owned steel capacity. It also participated with private capital in establishing a refinery and a lubricants plant but did not agree to the expansion of the privately owned refineries.

The Government took some action to encourage imports of machinery for use in coal mines and showed awareness of problems in the existing system of distribution and pricing of iron and steel in India. Government actions included establishment of the Government-owned Mineral & Metals Trading Co. in October to take over from the State Trading Corp. the functions of exporting ores and minerals, importing of ferrous and nonferrous metals and alloys, and implementing barter deals which the Government may specify. This firm handles all iron ore exports to Japan. New royalty rates were announced on August 27 on an additional group of ores by an amendment to the Second Schedule of the Mines and Minerals (regulation and development) Act, 1957. The revision established fixed amounts per unit of weight for abrasive, barite, bauxite, china clay, corundum, garnet, glass sand, kyanite, ocher, quartz, and steatite. The royalty payable on ores of precious metal, copper, lead and zinc remain on a percentage of pithead value.

The Mines Act, 1952, the Mines and Minerals (regulation and development) Act, 1957, and the Mineral Concession Rules, 1960 were applied to Goa, Damau, and Diu canceling a number of taxes and custom duties which were previously levied on iron ore exports and paid by mineowners. However, Section 16 of the Mines Act, 1952, which refers to the modification of existing leases, will—for the present—not be applicable to Goa.

PRODUCTION

The most significant trend in mineral production of India during 1959–63 has been increases in the output of iron and steel and raw materials such as coal, iron ore, and refractory materials needed in steel production. During 1959–63 production of coal, iron ore, and steel ingots increased by 38 percent, 87 percent, and 242 percent, respectively. Bauxite and aluminum had the highest increase rate among ores and metals. Production of some minerals such as manganese,

Digitized by Google

mica, and ilmenite which have traditionally been produced for export have declined because of increased competition from other sources.

Rise in construction (dams, roads, plants, and factories) is reflected by increase in cement and limestone output. Production of other nonmetallic minerals such as barite, fire clay, china clay, gypsum, kyanite, magnesite, and salt also generally has increased over the 5-year period.

Petroleum production trend is upward, both in the oilfields of Assam and in the Ankleswar field in Gujarat State, the latter starting regular crude shipments to Burmah-Shell and Esso refineries in February 1962. In 1962 Ankleswar crude constituted about 34 percent of total output.

[5] Processed.

TRADE

In 1963 the value of India's export of minerals was equivalent to US$111 million, that of metals and scrap to US$17 million, and that of petroleum products to US$12 million, giving a total of US$140 million (US$112 million in 1962) for all minerals and metals, or 6 percent of value of all exports. An important factor in the increase of mineral export value was the inclusion of exports of Goa in Indian trade statistics for the first time.

Principal minerals exported in 1963 were iron ore (US$66 million), mica (US$18.6 million), manganese ore (US$17.2 million), and petroleum products (US$12.2 million). Ferromanganese, pig iron, iron and steel, and aluminum constituted principal metal exports. Japan was the major buyer of Indian minerals, accounting for 45 percent of total mineral exports, followed by Czechoslovakia (8 percent), United States (7 percent), United Kingdom and West Germany (5 percent each), and Pakistan, Poland, and Rumania (4 percent each). Minerals (mainly iron ore, manganese, mica, bauxite, chromite, and salt) play an important part in trade between Japan and India, accounting for a third or more of India's exports to Japan.

At yearend, shipments of iron ore from India (exclusive of Goa) to Japan were governed by a 2-year agreement signed in May 1963 between State Trading Corp. and 10 major Japanese steel companies whereby the Japanese firms agreed to buy, at US$10.22 per ton, 2.2 millions tons of ore in 1963–64 and 2.25 million tons in 1964–65. Two previous agreements provide for export of 6 million tons of Indian iron ore to Japan per year starting in 1966. Other agreements concluded in 1963 provide for the export of 600,000 tons of iron ore to Rumania and 800,000 tons to Czechoslovakia.

A program prepared by the Ministry of International Trade of India aims toward attaining an export target of 30 million tons of iron ore by 1970–71. Achievement of the target would require considerable expansion of transportation and port facilities.

In 1963 the total value of tabulated imports was approximately US$532 million (nearly a quarter of total imports) distributed as follows in million U.S. dollars: petroleum 208; iron and steel 181; nonferrous metals (aluminum, copper and copper alloys, lead, tin, zinc, silver and platinum group, and miscellaneous) 114; and ores and minerals (unprocessed) 29. Among the nonferrous metals in terms of value, copper and its alloys constituted the most important item (US$55,500,000), followed by zinc (US$19,897,000), aluminum (US$14,100,000) and tin (US$11,450,000). In the foreseeable future, India will continue to depend on imports to meet all or a major portion of its requirements of nonferrous metals except aluminum.

Nearly one-third of the import value of unprocessed minerals was accounted for by sulfur, of which three-fourths was used for making sulfuric acid. Some of the other mineral imports, in order of importance, were asbestos, phosphates, sodium nitrate, borax, cryolite, fluorspar, and gypsum.

The United States has been an important supplier of iron and steel and some of the nonferrous metals, as well as sulfur. A determining factor in this trade has been a number of nonproject low-interest, long-term loans which U.S. Agency for International Development has given to India. India could import a number of commodities including minerals and metals in using a US$240 million loan made available in February 1963.

COMMODITY REVIEW

METALS

India has excellent-to-adequate reserves of the major essentials for producing iron and steel and has five major integrated steelworks, four of which have rated capacities of 1 million tons or more. Necessary iron ore, chromite, coal, manganese, and limestone are available from Indian mines, and reserves of the metallic ores are sufficient to permit appreciable exports. The only significant steel industry raw material deficiencies are tungsten and nickel. India's consumption of these metals has been small because little alloy steel has been produced. This situation will change, however, when the 100,000-ton-per-year-alloy steel plant, started in June 1963, is completed.

India is not so fortunate with regard to mineral resources for producing major nonferrous metals (except aluminum) as it is with respect to iron and steel raw material resources. Bauxite reserves, estimated at 64 million tons in 1960, are adequate, and annual aluminum production capacity, 53,000 tons, is increasing. In 1963 domestic production met about two-thirds of the aluminum requirements and perhaps less than 10 percent of the lead requirements. No primary zinc or tin was produced. Requirements of these metals by 1965–66 are estimated as follows, in tons: aluminum 115,000; copper 150,000; lead 65,000; tin 10,500; and zinc 187,500.

Digitized by Google

Beach sand deposits of South India contain large quantities of ilmenite, monazite, rutile, and zircon; output of ilmenite and rutile has been significant.

Aluminum and Bauxite.—There was a 2-percent decline in bauxite production. Bihar continued as the leading producing State with 49 percent of the output followed by Gujarat which accounted for 32 percent.

Bauxite consumption was estimated at 427,000 tons, with the aluminum industry consuming 300,000 tons, the cement industry 75,000 tons, the chemical industry 25,000 tons, and refractory and abrasive usage accounted for 27,000 tons.

India's bauxite reserve is estimated by the Indian Bureau of Mines at 260 million tons, of which nearly 77 million is reported as high grade containing more than 50 percent alumina.

In 1963, India's aluminum supply (not allowing for stock changes) was 81,027 tons. Semimanufactures produced totaled 41,912 tons, including sheets and circles 21,224 tons, wire rods 12,730 tons, foils 2,255 tons, and rods and extruded sections 3,703 tons. Imports consisted of the following: ingots 6,292 tons, bars and rods 15,556 tons, sheets, plates and strips 974 tons, foil 438 tons, wire 732 tons, circles 460 tons, pipes and tubes 188 tons, and others 1,179 tons.

By yearend India had an installed annual capacity for 53,000 tons of aluminum ingots, which is expected to increase to 70,000 tons by the end of 1964. Increased aluminum output during the year resulted partly from new production obtained, starting in mid-1962, from the 20,000-ton-per-year plant of the Hindustan Aluminium Corp., Ltd., at Renukoot in Uttar Pradesh. This company is a joint venture of Birla interests and Kaiser Aluminum & Chemical Corp. In April 1963, the Export-Import Bank extended a US$5 million loan to the Hindustan Aluminium to finance the addition of a plant for making drawn, extruded, flat, and coiled products at the rate of 15,000 metric tons per year—6,000 tons of redrawn wire, 7,000 tons of sheets and plates, and 2,000 tons of extruded products. Total cost of the plant is to exceed US$11 million. The company also desires to add 40,000 tons per year to its ingot capacity and apparently has obtained Government approval.

The Indian Aluminium Co., Ltd., a subsidiary of Aluminium Ltd. of Canada and the oldest aluminum producer in India, started with the expansion of its Alipuram smelter in Kerala from 5,700 tons to 10,800 tons per year and the erection of a 2,500-ton-per-year foil plant at Kalwa near Bombay. The additional capacity at Alipuram is expected to be completed in 1964; the Government meanwhile approved the company's proposal to further enlarge the plant capacity to 15,800 tons per year. The company recently completed enlargement of its smelter at Hirakud to the present annual capacity of 20,000 tons. It produced alumina for both smelters at Muri in Bihar (55,000 tons alumina per year) and had its fabricating plant in Belur (with capacity to produce 16,800 tons of rolled products per year).

India's third primary aluminum producer, the Aluminium Corp. of India, completed expanding its aluminum smelter in Asansol, West Bengal, from 2,500 tons of aluminum ingots to 7,500 tons per year. Work continued on the 10,000-ton-per-year plant of Madras Aluminum

Digitized by Google

Co. at Salem in Madras, being built by Madras State with the collaboration of Montecatini. The plant was scheduled to start production in the second half of 1963.

India's aluminum production target has been set tentatively at 250,000 tons for the fourth 5-year plan. During 1963 there were press reports on projects for establishing a 20,000-ton-per-year plant in the vicinity of the Koyna hydroelectric plant with technical collaboration of the Vereinigte Aluminium Werke of West Germany and another plant with 30,000-ton capacity in the States of Maharashtra or Mysore. By yearend no progress had been made on either project. The Government also asked the Hungarian Government to submit a project report for a 25,000-ton-per-year plant to be established at Korba in Madhya Pradesh. The project, if approved will be implemented by National Industrial Development Corp., a Government corporation, but with Hungarian assistance.

Copper.—All primary copper was produced by the Indian Copper Corp., from three underground mines in the Ghatsila region of Bihar State. The concentrator and smelter are at Moubhandar.

In 1963 the Indian Copper Corp. mined 474,345 tons of ore averaging 2.225 percent copper. The decrease of 4 percent in ore output resulted from the lost time on account of breakdown in the ropeway which moves the ore from mine to mill.

The company's copper output does not show great variation. The small increase shown since 1960 resulted from addition to the mill in 1960. In June 1962 the company started building an electrolytic refinery with 8,400 tons annual capacity; this plant is scheduled to be completed by December 1964. Imported blister copper will be used as raw material for the refinery. In addition, the Government approved plans by the company to replace its obsolete smelter facilities at Ghatsila with a new plant with a capacity of 16,500 tons per year of fire refined copper. This new plant will treat concentrates from increased ore production from the corporation's mines. Sulfuric acid also will be produced.

Copper imports were principally electrolytic wire bars 32,365 tons; ingots and billets 37,803 tons. Copper tubes, sheets, and strips and other products accounted for the remainder. Principal consumers were brass mills and manufacturers of cables, but defense needs increased during the year and demand was estimated at 115,000 tons compared with the total imports and production of 82,000 tons. As a result, prices of copper increased. Price of copper averaged US$1.28 a kilogram in 1962; in November 1963 it was reported at US$1.37. Domestic scrap and clean wire averaged US$1.30 per kilogram.

Exploration for copper deposits has been stepped up in the last few years to improve India's self-sufficiency. The Indian Bureau of Mines has carried out diamond drilling in the Khetri and Daribo deposits in Rajasthan and was investigating the old Rakha copper mine in the Ghatsila copper district and Dikchu in Assam. The National Mineral Development Corp. (a Government-of-India entity) has the responsibility for developing the Khetri mine with Western Knapp Engineering Co. serving as consultants. In conjunction with the mine development, construction of a 21,000-ton-per-year electrolytic copper refinery is projected, with production to start in 1965. Estimated cost of mine

Digitized by Google

development, mill, and refinery is about US$40 million, exclusive of housing and roads. The rate of production envisaged at Daribo is 1,500 tons of metal in concentrates which would be shipped to Khetri. Implementation of the Khetri project was slow because of lack of funds.

Gold.—Kolar Gold Fields and the Hutti mines in Mysore State were the only producers, accounting for about 85 and 15 percents of the 1962 gold output, respectively. Both mines are high-cost producers; in Kolar the gold produced costing nearly twice the international price. The Central Government took over the Kolar Gold Field in December 1962, but the Mysore Government still holds 96.5 percent of shares of the Hutti mine.

Average grade of gold mined in the three mines of Kolar Gold Fields was 5.69 grams (0.18 ounce) per ton compared with 7.07 grams (0.22 ounce) in 1962. Under a US$3.15 million modernization program, a new mill was put in operation at the Nundydroog mine, increasing grinding capacity from 21,000 to 28,000 tons per day and obviating the need of shipping some ore from this mine to Champion mine for milling. On basis of an encouraging report, the Mysore mine started sinking three new shafts in a new mining area.

Ore production at Hutti is to be increased from 350 to 1,000 tons per day. Necessary milling facilities will be added.

Efforts to combat illegal gold imports in order to reduce the outflow of foreign exchange, and attempts to find means of employing large private gold holdings for economic development reengaged the attention of the Government in late 1962 and 1963. These actions were prompted by the emergency created by the Chinese invasion. In September 1962 a bill was passed enabling the Government to control the supply, production, and distribution of gold, to ban future trading in gold, and to limit the purpose for which gold could be purchased. In November 1962, 15-year "gold bonds" were issued at a 6.5 percent interest rate. These bonds were to be bought with gold valued at world prices and would be redeemed in rupees. These actions at first brought down the price of gold—the average price for spot gold in Bombay declined from US$78.66 to US$60.58 per ounce, but the trend was reversed in December, the price rising to US$73.32 per ounce. On January 9, 1963, the Government promulgated "Gold Control Rules" which put restrictions on the free market in gold.

Iron Ore.—High-grade iron ore reserves are estimated to total 21,300 million tons and constitute perhaps a third of the world total. The low-grade reserve has not been determined but probably is large. Nearly one-third of the high-grade ore is in the States of Bihar and Orissa, relatively close to India's most important coalfields. These iron ore deposits supply four of India's steel plants. Large deposits of high-grade hematite exist in Madhya Pradesh State; one of these is mined to supply ore to the Bhilai steel plant. Other ore-rich regions of India are located in Mysore State, in Goa, and at several other points near the west coast.

Iron ore forms the bulk of India's nonfuel mineral production. Output in the last decade has more than trebled to meet the requirements of the expanding iron and steel industry and the export trade. In 1963 of States of Orissa, Bihar, Mysore, and Madhya Pradesh produced

Digitized by Google

40 percent, 23 percent, 16 percent, and 16 percent of the total, respectively. Nearly half of the 1962 production was obtained from 5 mines and an additional 27 percent from 16 mines. The remainder was distributed among 248 mines which produced from 500 to 100,000 tons in 1962. All the mines are opencast and about six are fairly well mechanized. Currently more than half of the output is obtained from privately owned and operated mines.

The National Mineral Development Corp. continued its activities in developing the Kiriburu and Bailadila deposits which will supply iron ore to Japan; Kiriburu will also supply the Bokaro steel plant when it is built. With removal of 340,000 cubic meters of overburden by yearend, stripping at Kiriburu was 82 percent completed. Production is expected at Bailadila by 1966 when, according to a 1960 contract, the Government will ship annually 4 million tons of ore from this deposit to Japan.

The railroad from Kiriburu to Visakhapatnam was completed, but mechanical stacking and loading facilities were not expected to be ready before April 1965. When completed, the material handling facilities will be able to dump 2,000 tons of ore per hour from railroad cars, and two loaders, each with 1,500-ton-per-hour capacity, will load ships. Eventually, the port will be able to handle 8.2 million tons of iron ore per year.

With a view of future expansion of iron ore exports the Government of India in February 1963 announced its decision to undertake the development of iron mines in the Tomka-Daitari-Kayagarh area and a port at Paradip in Orissa with Japanese technical and financial assistance. The project is to be completed in two stages. The first stage, estimated to cost US$63 million, envisages development of the mines, construction of a 160-kilometer road from the mines to the port, and erection of three berths for bulk ore carriers from 40,000 to 60,000 dead weight tons. This will allow the port to export 2 million tons of iron ore annually. In the second stage, further development of port facilities, improvement of the road, and construction of a 270-kilometer railway line from Kayagarh will be undertaken. With the completion of the second stage the port will reportedly be capable of handling iron ore exports of 5 to 10 million tons each year. A team of Japanese experts was to arrive in India to discuss further details of the collaboration. In November the Minister of International Trade submitted a plant which would increase iron ore exports to 30 million tons by end of the third 5-year plan in 1966. The developments at Paradip and the mines it would serve were included in the master plan.

Iron ore mining in Goa with Japanese financial and technical assistance showed a spectacular growth during 1950–60 in response to good market demands. The industry was, however, experiencing some difficulty in 1963 because of insufficient export orders, and many of the small mines were closed. The State Trading Corp. established an office in Goa with a view to assisting small mines, and presumably this function will be continued by the Mineral & Metal Trading Corp.

Prices of Goan iron ore were fixed by the Government of India effective May 28, 1962. These prices per metric ton f.o.b. vessel varied from US$5.41 for 55-percent ore to US$12.47 for 65-percent ore. These floor prices were lowered for 55 to 58-percent ore in January 1963

Digitized by Google

to US$5.25 to US$5.90 with further reduction (US$5.10 to US$5.70) permitted when 20 to 30 percent of total quantity of ore shipped against a contract was exported on Indian vessels. When quantities shipped on Indian vessels were 50 percent of the total quantity of an export contract, minimum prices would still be lower US$4.85 to US$5.45 per metric ton.

Iron and Steel.—In view of the favorable raw material base and the great need of the country, construction of steel plants received a high priority in India's second 5-year plan (1956–61). In 1963 India had an installed capacity for producing a little over 6 million tons of crude steel and 4,265,000 tons of finished steel. Roughly half of this capacity was in public sector plants; the balance was under private ownership. The Government-owned plants, managed by Hindustan Steel Ltd. (HSL), are Durgapur in Bihar State, Rourkela in Orissa State, and Bhilai in Madhya Pradesh State. Durgapur and Rourkela each have about 1-million-ton capacity; Bhilai's capacity is closer to 1.2 million tons. The 3-million-ton, privately owned capacity is distributed two-thirds Tata Iron & Steel Co. (TISCO) and one-third Indian Iron & Steel Co. (IISCO). The Mysore Iron and Steel Works (MISW) owned by Mysore State had 85,000-ton capacity. There is some degree of specialization of products among the three Government-owned plants; Bhilai concentrates more on heavy structurals, Durgapur makes merchant mill products and light structurals, and Rourkela produces only flat products. The Jamshedpur plant of TISCO, which is still the largest in India, produces a wide range of products. Both Bhilai and the steel plant of IISCO at Burnpur produce pig iron in addition to their own requirements for sale.

Production.—Of the pig iron produced in 1963, 4,831,000 tons was basic pig iron, 1,379,000 tons was foundry pig iron, and 393,000 tons was of other types; 1,184,023 tons was available for sale to founderies. Raw materials used by the steel industry included about 10.6 million tons of iron ore, 9.4 million tons of coking coal, 942,000 tons of non-coking coal, 2.9 million tons of limestone, 780,000 tons of dolomite, 831,000 tons of scrap, and 277,000 tons of manganese ore. For the first time oil injection was tried in one of the blast furnaces in Jamshedpur with favorable results. The experiment is of great interest to other producers because it offers a means of reducing coke consumption.

Production of steel ingots increased by 20 percent. The steel ingots were produced in basic open-hearth furnaces, except in Rourkela where three-fourths of the 1 million-ton steel capacity is in oxygen LD furnaces.

All classes of rolled steel with the exception of skelp registered increases. Rolled steel output included 1,009,700 tons produced by secondary producers and rerollers which produce rolled steel from billets and semifinished steel and from scrap, respectively.

Supply and Demand.—For a number of years the supply of steel in India has not been sufficient to meet all demands of the economy. Imports are limited by available foreign exchange. Large steel imports were arranged during the year by utilizing a U.S. loan and credits provided by United Kingdom, Austria, and Netherlands for steel, particularly plate, imports.

Source: Iron and Steel Control, Monthly Bulletins for January to December, 1961 and 1962. Ministry of Steel, Mines and Heavy Engineering, Department of Iron and Steel, Calcutta.

In 1963, with imports of 1,041,000 tons, total rolled steel available to the economy was 5,298,000 tons (not taking stock changes into account) compared with an estimated demand of 5.6 million tons. It is believed that there were heavy stocks of semifinished steel and heavier sections in the mills during part of 1963 which may have decreased the effective supply. There were critical shortages of certain items.

Shortages of pig iron led to partial curtailment of foundry production in certain parts of India. Against annual requirements of 2 million tons, only 1,184,000 tons was available for sale.

There have been many estimates of anticipated steel demand in India. The National Council of Applied Economic Research placed

Digitized by Google

the demand in 1965–66 as 6.9 million tons of rolled and mild steel equivalent to 9.7 million tons of ingots. The corresponding figures for 1970–71 are 13.6 million tons and 18.3 million tons, respectively. It is expected that the imbalance of supply and demand will continue in the third 5-year plan and in 1965–66 there will still be a deficit of 1.2 to 1.3 million tons of finished steel. In shortest supply will be plates, hot-rolled sheets and strips, cold-rolled sheets and strips, and galvanized sheets.

Distribution.—The Government of India, in September 1962, appointed a four-man committee to study the existing system of production, pricing, planning, and distribution of iron and steel. The committee found that the current cost-plus method of fixing steel prices does not allow for plant replacement and does not reflect the real costs of producing different sizes and categories of steel. The committee suggested categorization of steel demands into priorities and the establishment of a free market for nonpriority steel. It also urged the abolition of present system of distribution controls. It recommended that the authority to fix the retention price (price the steel producers are allowed to retain, which is established at some level in excess of production cost) should be removed from the Tariff Commission and entrusted to a Joint Plant Committee composed of the general manager of each plant with the Iron and Steel Controller as chairman. The Government has accepted most of the recommendations of the Committee, and a revised system of control and pricing was to become effective March 1, 1964.

In June the Government announced the following increase in the retention prices:

	Steel	Pig iron
Apr. 1, 1962 to Mar. 31, 1962	US$2.10	US$1.26
Apr. 1, 1963 to June 30, 1963	US$1.68	US$0.84
From July 1, 1963	US$2.10	----------

The increases were granted because of higher royalties on iron ore, limestone and other raw materials, statutory increase in price of coal and railroad freight, and increase in war-risk insurance. Selling price of steel was also increased by US$2.10 per ton on July 1, 1963, and that of pig iron of all grades by US$6.30 as of January 4, 1964.

Expansion Program.—India had planned to expand the steel capacity by 1966, the last year of the third 5-year plan, to 10.36 million tons of steel ingots and 6.91 million tons of finished steel. In view of the delay in starting construction of a new plant at Bokaro latest information sets the target at 9.375 million tons of steel ingots. The new capacity is to be achieved by the expansion of the three existing Government-owned plants to 5.9 million tons (Bhilai 2.5 million, Durgapur 1.6 million, and Rourkela 1.8 million). The Government has agreed in principle to let Indian Iron & Steel Co. expand to 310,000 tons of steel ingots, which will be the first stage in a 1-million-ton expansion program. Tata Iron & Steel Co. is expected to be allowed to expand only marginally.

TABLE 6.—Expansion of existing iron and steel plants and construction of new facilities

Plant	Projected capacity (million metric tons)	Expansion cost (million dollars)		Anticipated completion date	Remarks
		Foreign exchange	Total		
Bhilai	2.5	(1)	(1)	1965	Construction of coke oven and blast furnace started.
Rourkela	1.8	100	100	1966	Loan agreement between India and West Germany for $100 million signed in April 1963. The credit will be for 20 years at 5.75 percent interest with a grace period of 7 years.
	0.1 tinplate	117.6	273	(1)	Contract for installing an electrolytic tinning line awarded to Demag.
Durgapur	1.6			1965	Construction of blast furnace started in August.
Burnpur	1.31 and 2.0	12.8	25.62	(1)	Financing of the foreign exchange cost is expected to be by a loan from International Bank for Reconstruction and Development.
Jamshedpur	2.03	22.5	38	(1)	Do.
Durgapur [2] (alloy steel plant).	0.1	46	140.7	1966–67	Of the foreign exchange cost, $40 million will come from Japan's Aid-India consortium pledge and $3.25 million will be financed from a special credit from the Canadian Government's Export Credit Insurance Corporation. Cornerstone of the steel smelting shop laid in June 1963 and completion is expected during 1966–67.

[1] Data not available.
[2] New plant.

In 1963 expansion of Bhilai Steel Plant was well underway and that of Rourkela was formally inaugurated in August. Subsequently, work started at Durgapur on the foundation for a new blast furnace.

Construction of a new steel plant with an initial capacity of 1 million tons at Bokaro in Bihar State was envisaged for the third 5-year plan. Beginning in July 1962 a team of experts from the United States Steel Corp. went to India in behalf of U.S. Agency for International Development to make a feasibility study of this plant. Their report, presented to the Government of India on April 8, 1963, proposed a plant with an initial capacity of 1.4 million tons, thereafter rising in two stages to 4 million tons by 1977. The report recommended management for the plant independent of Hindustan Steel Ltd. during an initial 10-year operating period and suggested further studies of raw material supplies. The costs were estimated at US$920 million for the initital stage, US$245 million for the second stage, and US$340 million for the final stage. The proposed plant would produce flat products.

In India it was hoped and even expected that Bokaro would be built with U.S. aid. The Director of AID announced at the end of July that no decision would be taken regarding U.S. aid in 1963. It was also made clear that any assistance to Bokaro would have to come from the overall American assistance to India. Subsequently, the Government of India withdrew its request for U.S. aid for the Bokaro Steel Plant. Although plans for the construction of this plant are actively

Digitized by Google

pursued, the Indian Government has now abandoned the expectation of realizing output from Bokaro during the third 5-year plan.

Hindustan Steel Ltd. issued a letter of intent to a group of five Japanese companies for construction of 100,000-ton-per-year alloy steel plant in Durgapur. The letter of intent accepted the Japanese firms' proposal covering the design, supply, erection, and commissioning of plant and equipment for 9 of the 11 sections into which the project had been divided. The Amco Furnace Constructors Ltd. of Rexdale, Ontario, will design, supply, erect, and commission the three heating furnaces and soaking pits. The bid for a fourth heating furnace was still pending in June.

Alloy steel plants were being built also by Bagla Alloy Steel Ltd. at Kanpur, Uttar Pradesh, Mahindra Ugine Steel Co. at Khapoli, Maharshtra, and Firth Sterling Steel Co. near Thana, Maharashtra.

Tata Iron & Steel Co., the only producer of silicon sheets, received Government approval for expanding its 24,000-ton-per-year capacity to 42,000 tons. Proposals were considered for a 20,000-ton-per-year silicon-steel facility adjunct to the existing hot and cold-rolling facilities at the Rourkela plant.

To meet the need for foundry pig iron which cannot be fully met by the large integrated steel plants, the Government of India has issued licenses for small plants to produce 540,000 tons of pig iron. In 1963 only one 30,000-ton-per-year unit in Barabil was actually producing, and another unit of 12,000-ton annual capacity was built in the Chanda district of Maharashtra and may have started production. The other licenses have not been utilized.

Lead-Zinc.—In 1963 the Metal Corp. of India continued to be the sole producer of lead-zinc ore and lead metal. It mined about 500 tons of ore per day (average grade 3.03 percent lead, 4.41 percent zinc) from its Zawar mine in Rajasthan. The company also produced 5,920 tons of lead concentrate with 72.9 percent lead and 5.64 percent zinc, and 10,627 tons of zinc concentrate with 55.14 percent zinc and 1.52 percent lead. The lead concentrate was smelted at the corporation's smelter in Tundhoo in Bihar; 11,680 tons of zinc concentrate was shipped to Japan for custom smelting. The ore is argentiferous and in 1963, 118,315 ounces of silver was recovered at the Tundhoo plant. To increase daily production to 1,500 to 1,700 tons of ore a new 30-meter shaft is being sunk at the mine and is expected to be completed in late 1964. A rich deposit with 10 percent zinc and 2 percent lead was reportedly discovered at Balaria, a few kilometers from the present mine; the reserve was estimated to be 25 million tons.

Imports of lead and zinc are mainly ingots. Lead imports in 1963 consisted of 32,652 tons of pig lead, 2,793 tons unwrought lead, 554 tons of antimonial, and the remainder (98 tons) bars, pipes, tubes, and sheets. Zinc imports were comprised of 81,306 tons of slab, 3,280 tons of zinc base alloys, 349 tons of sheet and strips, and 1,109 tons of others. Lead was used principally for making batteries, paints, and alloys (each about 7,000 tons per year) and cable (1,000 to 2,000 tons per year). Estimated consumption pattern of zinc is as follows: Galvanizing 28,000 to 30,000 tons, brass and other alloys 22,000 to 25,000 tons, and zinc oxide 8,000 to 10,000 tons per year. Prices of lead

758-002—65——84

Digitized by Google

and electrolytic zinc averaged 46 and 53 cents per kilogram, respectively.

A number of steps have been taken or envisaged to increase domestic production of lead and zinc. The Metal Corp. of India, in addition to its program to increase ore production from the Zawar mine, is also building an electrolytic zinc plant near Udaipur to produce 18,000 tons of zinc and from 70 to 80 tons of byproduct cadmium annually. Its lead smelter at Tundhoo is also being expanded to produce 8,500 to 10,000 tons of metal per year. Consolidated Mining & Smelting of Canada and Metal Distributors Ltd. of Calcutta have formed Cominco Binani Zinc Ltd. This firm will build a 20,000-ton-per-year zinc smelter in Edayar near Alwaye in Kerala State; imported zinc concentrates will be used. Byproducts will include 45,000 tons of sulfuric acid and 30 to 40 tons of cadmium. This refinery was scheduled for mid-1966 completion.

Manganese Ore.—The generally declining trend in India's manganese ore production since the mid-1950's continued in 1963. Production was 55.6 percent of the maximum production achieved in 1953. It is estimated that 70 percent of the output was 35 percent manganese ore or higher grade which, in the majority of mines, is brought up to grade by hand cobbing. Orissa was the largest producing State with 31 percent of total output. Other producing States and corresponding percentages of total output were: Mysore 22; Madhya Pradesh 22; Maharashtra 14; Andhra Pradesh 5; Gujarat 2; and Bihar 2. Manganese is also produced in Goa.

Reserves of all classes of manganese ore in India were estimated in 1956 to total more than 100 million tons of mine-run ore, equivalent to about 60 million tons of marketable ore. Much of the ore is of metallurgical grade, but low-phosphorus ore is limited. Principal mines are in the States of Madhya Pradesh and Maharashtra.

In 1961, there were 416 manganese mines in India, with an aggregate average daily employment of 46,923. It is believed 1963 figures are lower. The majority of the mines were small surface operations, but there were about 12 fairly large mines, mainly owned by Manganese (India) Ltd. Principal manganese producers in India and their important mines were the following:

Company:	*Principal mines*
Manganese (India) Ltd	Balaghat, Ukwa, Dongri Buzurg, Tirodi, and Chikla in Madhya Pradesh, and Kandri and Mansar in Maharashtra.
Tata Iron & Steel Co., Ltd	Joda West.
R. B. Seth Shreeram Durgaprasad	Gowari-Wadhona in Madhya Pradesh.
Shivrajpur Syndicate	Bamankua and Pani in Gujarat State.
The Jeypore Sugar Co., Ltd	Mines in Orissa.
Agarwal, R. S. Seth Gopikishan	Mine near Tirodi in Madhya Pradesh.
Orissa Mineral Development Co., Ltd	Mines in Orissa.
Serajuddin & Co	Do.
M. A. Tullock	Barabil, Orissa.

Manganese (India) Ltd. was formed in 1962 with the Government of India and the State Governments of Madhya Pradesh and Ma-

Digitized by Google

harashtra holding 51 percent of the shares and the British firm, Central Provinces Manganese Ore Co., 49 percent. The latter for many decades had been India's largest producer.

Manganese exports increased from the 1962 level, which was the lowest during the last decade. In spite of the rise, 1963 exports were only 53 percent of the maximum achieved in 1957. New sources of manganese in Africa and Brazil and higher cost of Indian manganese have been the reasons for decline in Indian exports. The US$40 million barter agreement concluded between the United States and India in June 1963 will be of great assistance to the industry. The agreement provides for exchange of agricultural products (90 percent cotton) for approximately 300,000 tons of manganese, 130,000 tons of high-carbon ferromanganese, 6,000 tons of beryl ore, and a minimum of US$2 million of mica block and film.

In 1963 prices of manganese ore with 46 to 48 percent manganese (f.o.b. Indian ports) ranged from US$19.95 to US$22.47 per ton. Average price for other grades was as follows: 42 to 44 percent, US$18.45; 40 to 42 percent, US$16.85; 38 to 40 percent, US$12.47; and 30 to 32 percent, US$8.82. There has been a steady decline in the price of manganese ore exported from India; the 1956 price of high-grade ore was about US$53.

Decline in the export of manganese is partly offset by increasing consumption by the domestic iron and steel and ferromanganese industry. Current consumption for all uses is about 400,000 tons per year.

Mineral Sands.—The large beach deposits of Kerala in South India constitute a large and rich source of ilmenite, monazite, rutile, and zircon. Thorium nitrate and rare earths chlorides and crabonates are produced from processing monazite at the Rare Earths Factory at Alwaye. The thorium salt is further processed for extraction of uranium.

By quantity, ilmenite is the most important mineral produced from India's mineral sands deposits extending from Quilon to Cape Comorin. Production has been declining because of the industry's inability to find export markets. Presence of a small amount of chromite has also adversely affected the marketability of Indian ilmenite. Production was only about one-fifth of that of 1962, and exports declined 24.5 percent. As of December 1962 stocks of unsold ilmenite totaled 300,000 tons. Domestic consumption is limited to less than 10,000 tons used in the plant of Travancore Titanium Products Ltd. (controlled by the Government of Kerala State) at Trivandrum which manufactures titanium paints. The company has been licensed by the Government of India to increase titanium dioxide production by 50 tons per day from the present level of 18 tons per day. Expansion is to be achieved in two stages.

The capacity of the monazite processing plant at Alwaye was increased to 3,000 tons per year of monazite in late 1962, and monazite output has reached this level. Apparently India is able to market readily the rare earths chlorides produced at the Alwaye plant. Thorium hydroxide from the plant is treated at the plant of Indian Atomic Energy Commission at Trombay near Bombay where thorium nitrate, thorium oxide, and uranium fluoride are produced.

Digitized by Google

Silver.—Of the total silver produced in India in 1963, Metal Corp. of India accounted for 118,315 troy ounces recovered from lead concentrate of the Zawar mine. The remainder was a byproduct of refining gold produced at Kolar Gold Field. Silver was not imported. Prices ranged from US$1.31 per ounce in January to US$1.50 in December, averaging US$1.38 per ounce.

NONMETALS

India has outstanding resources of sheet mica. High-quality refractory minerals such as fire clay, quartzite, magnesite, kyanite, and sillimanite are also available. Much of the industry for manufacturing fire clay refractories and silica brick is near the coalfields of the Bihar-Bengal area where the raw materials are found.

India is deficient in many industrial minerals such as chrysotile-grade asbestos, borax, fluorspar, and sulfur. Fertilizer raw materials (phosphate rock and potash) are completely lacking, except for some apatite deposits.

Cement.—There were 36 cement plants in India with an annual installed capacity of nearly 10 million tons; all but one of these plants was privately owned. The largest producer was the Associated Cement Cos. with 14 plants and 40 percent of the output. Production in 1963 was not sufficient to meet all demands. Inadequate fuel and power supplies and insufficient transportation facilities for moving the cement have at times adversely influenced production.

As of the beginning of the year, licenses for establishing 22 new plants(annual capacity 4.7 million tons) and expansion of 12 existing plants (1.95 million tons additional capacity) were in force. Additionally, seven other projects, with a total capacity of 1.5 million tons, had been approved but not yet licensed. If implemented on schedule, these licenses and approved projects will bring the capacity over the 1965–66 target of 15 million tons. Progress in the establishment of new plants must necessarily be limited by the available foreign exchange and the capacity of the domestic plants for making cement plant machinery, of which there were three in 1963.

The price of cement for sale in bulk is fixed by the Government of India on a uniform free on rail (f.o.r.) destination basis. For most plants the ex-works price of cement is US$15.17 per ton. The uniform f.o.r. destination price of unpacked cement is US$20.53.

Mica.—India normally produces 70 to 80 percent of the world's dressed mica (block, sheet, and splittings). The high quality of the raw material and ample supply of labor skilled in cutting, sorting, and splitting of mica gives India a unique position in this industry. The mica is produced principally in Bihar, Andhra Pradesh, and Rajasthan. In 1963 these States produced 45 percent, 28 percent, and 25 percent, respectively, of India's total output. Mica mines are numerous; 720 were listed in 1960. This year, however, 42 percent of the total crude mica output was reported from 50 mines, having an annual production capacity exceeding 140 tons. Principal producing companies are:

Digitized by Google

Andhra Pradesh	Krishna Mining Co. Tellabodu Co. (Private) Ltd. C.V.C. Mining Co. (Private) Ltd. The Premier Mica Co.
Bihar	Chrestien Mica Industries Ltd. Chatturam Horilram (Private) Ltd. The Indian Mica Supply Co. (Private) Ltd. S. K. Sahana & Sons Ltd. Eastern Manganese & Mineral Ltd.
Rajasthan	Duduwal and Co. Rajasthan Minerals & Co. Ram Lal Sons R.B. Seth Moolchand Nemichand (Private) Ltd.

Consumption of mica in Indian industries was estimated at 3,000 tons mainly of scrap resulting from dressing. Some of this scrap is utilized in the manufacture of micanite bricks and allied products.

During 1959–63, export of block mica generally declined but splittings and scrap exports have shown an increasing trend. As a result, value of mica exports declined to US$18.6 million, compared with US$22.45 million in 1962, although the tonnage exported was 9 percent higher. Mica splittings accounted for US$10.3 million of the value of all mica exports. A Mica Promotion Council was established in 1956 to bring stability and integrity in the mica trade and to establish better quality control.

The 1963 price of mica, per kilogram f.o.b. Calcutta, averaged from US$5.25 to US$69.30 for various grades of block mica and US$0.63 to US$5.25 for splittings, depending on quality.

In September 1963 the Bihar Regional Mica Convention passed a resolution recommending embargo on exports of mica waste, but at yearend the Ministry of International Trade had not acted upon the recommendation.

Salt.—Except for 3,400 tons of rock salt produced in the Mandi mines of Himachel Pradesh, all salt was recovered from sea brine. Principal producing States and their 1963 production were as follow: Gujarat 2,454,200 tons; Madras 868,600 tons; Maharashtra 462,700 tons; and Andhra Pradesh 266,200 tons. The remainder was produced in Orissa, Mysore, West Bengal, and Kerala. The third 5-year plan envisages a production of 6 million tons of salt by 1965–66. The bulk of the salt is for human consumption, although industrial use is increasing rapidly.

Sulfur and Pyrite.—The sulfuric acid industry (1961–62 production 436,000 tons, 1965–66 target 1.5 million tons) is based almost entirely on imported elemental sulfur, and consumes 75 percent of the imports. Sulfur requirements, currently about 200,000 tons per year, are expected to increase to 500,000 tons by 1965–66. Gypsum for production of ammonium sulfate is used at the Sindri fertilizer plant. However, the gypsum obtained from the Bikaner deposits in Rajasthan has not been suitable, and in 1962 India was importing gypsum from Pakistan. Reportedly Sindri will change to the conventional process of using sulfuric acid in production of ammonium sulfate.

Digitized by Google

The Indian Bureau of Mines has for some years been examining the Amjor pyrite deposit to determine ore reserves and plan a mining system. The Government-owned Pyrite and Chemicals Development Co. was established in 1960 for the exploitation of the deposit, with a view to recovering elemental sulfur from the pyrite and using the pyrite as is in production of sulfuric acid. The Central Fuel Research Institute reportedly started erection of a pilot plant of 1-ton-per-hour capacity for the recovery of elemental sulfur from pyrite.

MINERAL FUELS

India's energy requirements are met by bituminous coal and lignite, petroleum, hydroelectric power, wood, and animal and agricultural waste. The reserves of coal of all types in India in seams of 4 feet and over up to a depth of 2,000 feet were estimated in 1956 at about 43,000 million tons. This comprises 39,000 million tons of Gondwana (bituminous coal) and 4,000 million of Tertiary (noncoking coal). Of the Gondwana reserve, metallurgical coal, found largely in the Jharia, Raniganj, Giridih, and Bokaro fields of Bihar and West Bengal, comprises about 2,000 million tons. Other coalfields are in Madhya Pradesh and Andhra Pradesh States. The largest lignite deposit is at Neyveli in Madras State, and there are Tertiary coal seams in Assam. Concentration of much of the coal output in a small area of northeast India adds to the price of coal in south and west India.

Although coal is the dominant source of commercial energy, petroleum consumption has increased rapidly. Adequate distribution facilities make petroleum products readily available throughout India. In spite of increasing production, India will remain an importing country in the foreseeable future with more of the imports as crude.

India's hydroelectric potential is estimated at 41 million kilowatts. Installed hydroelectric capacity in 1961 was 1,650,000 kilowatts of a total installed electric production capacity of 5,590,000 kilowatts—the difference accounted for mainly by coal consuming plants. Planned capacity for 1966 is 12,660,000 kilowatts with hydroelectric plants accounting for 5,070,000 kilowatts and coal 7,130,000 kilowatts.

Coal.—*Production and Consumption.*—Both in tonnage and value, coal was the most important mineral commodity produced and continued as India's principal energy source. Coal accounted for nearly three-fourths of the value of mineral output. Production exceeded demand. Pit-head stocks at yearend were 4.72 million tons compared with 3.48 million at the end of 1962; stocks held by consumers totaled 4.4 million tons. Of the total output, 17.5 million tons were coking coal.

In 1962 output per man-shift in coal mines of India was 1.26 tons for miners and loaders, 0.67 ton for all underground and surface workers, and 0.46 ton for all workers; the latter figure increased to 0.51 ton in 1963.

TABLE 7.—Energy consumption 1960–61

Source	Consumption		
	Million tons of coal equivalent	Commercial energy, percent	Total energy, percent
Commercial fuels:			
Coal	54.60	84.00	33.00
Oil	9.50	14.60	5.80
Hydro	.90	1.00	.60
Total commercial fuels	65.00	100.00	39.40
Noncommercial fuels:			
Cattle dung	46.00	----------	27.90
Fuelwood	35.00	----------	21.20
Agricultural waste	19.00	----------	11.50
Total noncommercial fuels	100.00	----------	60.60
Total	165.00	100.00	100.00

Source: M. S. Randhawa, "Assessment and Development of Natural Resources in India," United Nations Conference on the Application of Science and Technology for Benefits of Less Developed Countries. Geneva. February 4–20, 1963.

Bihar continued to be the leading producing State with 49 percent of the total output, followed by West Bengal (30 percent), Madhya Pradesh (12 percent), and Andhra Pradesh (5 percent). Orissa and Assam supplied the remainder.

Important consumers were railways (31 percent), iron and steel (19 percent), power (11 percent), cement and textiles (5 percent each), and cotton mills and paper mills about 3 percent each.

Because of declines in the demand for coal by industrial consumers, estimates of coal consumption by 1965–66, the last year of the third 5-year plan, were revised downward several times, the latest figure being 90 million tons. Of this total, requirements for coking coal were set at 20.4 million tons and for coal to be used to make soft coke for domestic use at 4.5 million tons. Railroads, power and cement plants are expected to require 20.0 million, 13.6 million, and 6.3 million tons, respectively. The fourth 5-year plan target for coal to be attained in the 1970–71 has also been revised downward from 180 million tons to 154.5 million tons.

Distribution.—The improved supply position in 1963 resulted not only from increases in output but also from improved transportation. Railroads were able to move more coal because competing demands on railroad cars were not as severe as before. Coal shipments by rail in 1963 totaled 53.2 million tons compared with 49.2 million tons in 1962. An additional 5.3 million tons were shipped by other means.

Transportaton of coal from mines and its distribution has not always kept up with mine production or requirements of the consumers, particularly the steel industry. The problem arose partly from insufficient railroad cars, long turn-around periods, and the heavy traffic on the Indian railroads in the coalfield area. Pipeline transportation of coal slurry has been considered as a means of supplementing existing facilities. In 1963 a team from the International Bank for Reconstruction and Development (IBRD) was in India to examine ways and means of improving coal transportation.

Digitized by Google

Principal Mines and Companies.—In 1963 there were 850 operating coal mines in India, with total average daily force of 434,000. Of these, 616 produce less than 100,000 tons, 41 over 200,000 tons, and 30 over 300,000 tons of coal annually. The 71 mines in the latter two groups accounted for almost 50 percent of total output. Coking coal was produced in 180 mines, almost all privately owned. The majority of the mines are underground.

TABLE 8.—Principal coal producing companies and their mines

Company	Date of establishment	Authorized capital (thousand Rs.)	1961 production (thousand metric tons)	Principal mines
Bengal Coal Co. Ltd	1844	12,000	3,200	Poidih, Parbelia, Banksimulia, Sitalpur, Sodepur, Murulidih.
Equitable Coal Co. Ltd	1863	4,000	1,800	Disergarh, Bejdih, Methani, Ranipur, Charanpur, Jamuria.
Burrakur Coal Co. Ltd	1901	15,000	1,300	Loyabad, Mudidih, Teetulmuri, Katras, Saltore.
East Indian Coal Co. Ltd	1893	----------	1,087	Bararee, Jealgora, Kenwadih, South Bulliari, Upper Mehtadih, Selected Jamburiya.
Amalgamated Coalfields Ltd	1924	3,000	1,004	Bhamori, Eklehra, Jatachappa, Datlawest, Rawanwara.
New Beerbhoom Coal Co. Ltd	1873	2,500	790	Kendah, Victoria, Bermondia, Bastacolla.
Bhowra Kankanee Collieries Ltd	1954	7,000	738	Bhowra, Amlabad, Pootkee, Kankanee.
Pench Valley Coal Co. Ltd	1905	3,000	529	Chandametta, North Chandametta, Barkui, Dongarchickli.
Raneegunge Coal Association Ltd.	1873	2,400	502	Kustore, Alkusa, Burragarh.
Katra Jharia Coal Co. Ltd	1893	1,500	350	Seebpore, Laikdih.
Western Bengal Collieries Ltd	1944	20,000	347	Moira, Samla Manderboni.
Tata Iron & Steel Co. Ltd	1907	308,622	1,697	Bhelatand, Choitodih, Bigwardih, Jamodoba, Malkera, Sijua.
Indian Iron & Steel Co. Ltd	1918	160,000	319	Jinagore, Chasnala, Noonodihjeetpur, Ramnagore, Het Kanra.

The publicly owned companies comprise the National Coal Development Corp. (NCDC) and the Singareni Collieries Co. Ltd. NCDC was established in 1956; its paid up capital of about US$29 million, is entirely subscribed by the Central Government. It operates mines in Bihar, Madhya Pradesh, Orissa, and Maharashtra. Andhra Pradesh State owns the majority of the shares of the Singareni Collieries Co. Ltd. which operates three coal mines all in this State. This company produced 3 million tons of coal in 1963.

Expansion and Development.—The third and fourth 5-year plans of India called originally for the following production targets:

Year	Production, million tons			Remarks
	Private mines	Publicly owned mines	Total	
1965-66	64.5	33.5	98	To include 18 million tons of coking coal.
1970-71	89.0	91.0	180	To include 58 million tons of coking coal.

Digitized by Google

Although these demands have been revised downwards, the NCDC still has to increase its production by perhaps 17 to 20 million tons to meet the 1965–66 target. This organization received assistance from France, Poland, the U.S.S.R., the United Kingdom, and the United States. The U.S. Agency for International Development has financed preparation of engineering plans and estimates for establishing opencast and underground mines in Ramgarh coalfield in Bihar, with total production of 1.5 million tons per year. This Agency is also financing the foreign exchange of ropeways for moving sand needed in stowing operations at Jharia and Raniganj fields of Bihar, but this assistance was not exclusively for NCDC. An agreement signed August 4, 1962, between NCDC and Tjazhpromexport, a supply organization of the Soviet Union, called for the Soviet Union to supply machinery and equipment valued at US$5.7 million as well as technicians to develop the Banki and Surakachar mines in Korba field of Madhya Pradesh. The goal of the project was for the mines to produce a total of 1.7 million tons of coal by 1965.

Another agreement in April 1963 between the same parties provided for development of an open-pit mine at Manikpur in Madhya Pradesh to produce 1 million tons. The U.S.S.R. will supply equipment worth US$1.58 million and technicians for the project. In September 1963 Tjazhpromexport contracted to establish a coal washery at Kathara with an annual capacity of 3 million tons of raw coal. The US$4.3 million equipment cost will be financed by the Soviet Union. Polish assistance is involved in sinking shafts and developing nine deep coal mines to produce coking coal. Development cost for each property will vary between US$31.5 million and $42 million, 30 percent of the costs to be supplied by Poland. Sudamih and Monidih in Bihar are the first mines to be developed, each with 2-million-ton-per-year projected output by 1972. The National Coal Board of the United Kingdom submitted a preliminary project report on a deep-shaft mine at Jarangdih also in Bihar, which is to be developed with United Kingdom assistance. The French contribution is modest (US$210,000) and will provide equipment and personnel to develop an NCDC property in Karanpurian where thick coal seams occur. In addition to the above, NCDC is starting or will start on the following projects, all located in Madhya Pradesh:

Mine	Total cost (million) dollars	Projected output (million tons)	Target date	Type of operation
Singrauli	31.5	2.54	1956–64	Opencast.
Bijuri	4.33	0.3	1963–64	(1).
Kathkona	5.46	(1)	(1)	(1).

[1] Not available.

Private industry is also scheduled to increase its output during the third 5-year plan, although not to the same extent as the publicly owned companies. The International Bank for Reconstruction and Development (IBRD) in August 1961 provided a US$35 million loan to the Government of India to be used by the private coal industry to

Digitized by Google

meet foreign exchange costs of purchases of equipment. By yearend, coal companies had placed orders for equipment worth US$27.4 million.

Coal Washeries.—Indian coals have a variable and high ash content, and coke made from these coals causes a high slag volume in the blast furnace. To improve the quality of coke, both the private and publicly owned steel companies have built and are continuing to build coal washeries. Seven existing washeries have a capacity of 9.25 million tons of raw coal, producing over 6 million tons of washed coal.

Addition of new washeries and modification of existing plants are scheduled to increase annual input capacity to 31 million tons by 1967–68, producing about 18.5 million tons of washed coal. One of these at Patherdih in Bihar was under construction and is expected to be in operation in mid-1964.

The largest existing washery, Dugda I, with annual throughput capacity of 2.4 million tons, was designed and fabricated by McNally Pittsburg of Pittsburg, Kans. This firm, in a joint venture with Bird & Co. (private) Ltd. of Calcutta, in 1961 established the McNally Bird Engineering Co. Private Ltd. for manufacturing component parts for coal washeries. Bird & Co. (Private) Ltd. is a large British-controlled Indian Managing Agency.

Government Regulations.—To assist the industry, the Government of India reduced import duty to 15 percent on machinery intended for the coal industry effective April 21, 1963, and later introduced a bill in the Lower House of Parliament (Lok Sabha) to amend the Income Tax Act so as to increase from the existing 20 percent to 35 percent the development rebate permissible in respect of certain machinery and equipment installed in a coal mine between April 1, 1963, and March 31, 1966.

Circular 23 entitled "Flameproof Apparatus and Equipment of Indigenous Make" issued in April 1963 to the Indian coal mining industry by the Chief Inspector of Mines in India stated that "* * * The Central Mining Research Station, Dhanbad, have now the necessary facilities to carry out tests on the flameproofness of an electrical apparatus or equipment and some of the indigenous-made apparatus and equipment have passed the necessary tests and approved by this office for use in gassy mines." It is understood that all coal mining equipment, whether imported or made in India, must first meet the Indian Standards Specifications, I.S. 2148 "Specification for Flameproof Enclosures of Electrical Apparatus" and protoypes of the equipment must then be tested by the staff of the Central Mining Station. The Indian Standards Institute is in the process of drawing up further standards and specifications for gathering-arm loaders, arc-wall coal cutters, conveyors, cutter picks, mine cars, axles, wheels, and couplings.

The Coal Board continued to extend assistance to collieries for sand stowing to improve extraction and safety. Payments made for this purpose during the fiscal year ending March 31, 1963, totaled US$4.4 million.

Coal Prices.—Pit-head prices of coal at yearend varied as follows, depending on grade:

Digitized by Google

	Run-of-mine, dust, and slack coal	Steam coal and nut size
Noncoking	US$3.78 to 5.18	US$3.98 to 5.41.
Coking	US$5.75 to 5.84	US$4.92 to 6.05.

During 1963, coal prices were increased three times. All these increases were connected with wage awards which had to be implemented from certain specified dates. The first increase of Rs0.80 (US$0.17) per metric ton was effected on March 1, 1963. The corresponding increase in the price of hard and soft coke was Rs1.07 per metric ton (US$0.22 per metric ton). The second increase of Rs0.49 (US$0.10) per metric ton was approved on April 1, 1963, to cover another wage increase. The third increase of Rs0.06 per metric ton (US$0.01) was allowed from June 1, 1963, to cover a step-in increase in wages of workers.

Lignite.—The Neyveli Lignite Corp. in Madras in May 1963 invited global tenders for the supply of machinery required to increase the production of lignite from the original annual target figure of 3.56 million tons to 4.88 million tons. The proposed increase in production is to meet the requirements of the Neyveli power station whose capacity is to be raised from 250,000 kilowatts (produced by five 50,000-kilowatt units) to 400,000 kilowatts through the installation of additional units. The integrated lignite project as originally planned envisaged production of 3.56 million tons of lignite to be used as follows in million tons: power generation 1.52; production of nitrogenous fertilizer 0.52; domestic and industrial fuel 1.52.

The lignite is mined in a very large opencast mine which started producing on a relatively small scale in 1961. Full production has not been attained, although output increased to 991,718 tons from 210,748 tons in 1962. The second, third, and fourth units of the powerplant were put in operation, and the last unit was to be completed early in 1964. A revised schedule calls for operation of the fertilizer plant by 1966 and of the briquetting and carbonization plant by 1965.

Petroleum.—*Exploration and Production.*—In 1963 the Oil and Natural Gas Commission (a stautory body set up by the Government of India in 1956) was the most active organization in petroleum exploration in India. On March 19 the Commission announced its decision to drill 120 wells in sedimentary basins of India. Greatest effort will continue in the Ankleswar-Kalol areas in Gujarat, but drilling will also be carried out in the Cambay field and in selected areas of Punjab, Madras, Bihar, and Assam. In the latter State, Oil India Ltd. (a 50–50 partnership between Government of India and Burmah Oil Co.) has obtained a license from the Assam Government to explore for oil in approximately 3,340 square kilometers (1,290 square miles) in the Doomdooma region of Lakhimpur district. The company has programed to drill 30 wells. The Government of India also showed interest in oil exploration in the Persian Gulf with the hope of developing a source of crude for its refineries.

In October 1963 it was reported that 154 wells had been drilled so far in the Ankleswar and Cambay fields: 80 producing wells, 17 gas wells,

Digitized by Google

41 being tested, and 16 dry. Reserves of Ankleswar were given as 45 million tons.

The large increase in crude oil production in 1963 (4.9 million barrels) resulted primarily from growing production in Ankleswar field.

Refinery production increased nearly 13.1 percent over that of 1962. The increase resulted principally from stepped up operations at the Esso and Burmah Shell refineries in Bombay.

Refineries which were operating at yearend had a total throughput capacity of 9.1 million tons of crude oil. Of this total, 750,000 tons of capacity was publicly owned (Gauhati in Assam), and the remainder was accounted for by the privately owned Burmah-Shell in Bombay 3,750,000 tons, Esso Eastern in Bombay 2,500,000 tons, Caltex in Visakhapatnam 1,600,000 tons, and Digboi in Assam 500,000 tons. In Barauni, a Government refinery was under construction with an initial capacity of 2 million tons to be expanded to 3 million tons annually.

Expansion of the Industry.—On April 27 the Government of India and Phillips Petroleum Co. signed an agreement for the construction of a 2.5-million-ton-per-year refinery at Ambalamukal, 10 miles south of Cochin port in Kerala. A company, Cochin Refineries Ltd., will be formed in which the Government of India will have 51 percent of the shares, Phillips Petroleum Co. 25 percent, and others, including private Indian investors, the remainder. In addition to this, a Government refinery will be built at Koyali (Gujarat) with an initial annual capacity of 2 million tons (two atmospheric units of 1 million tons each and a catalytic reformer) to be increased eventually to 3 million tons. As of late 1963, active construction of Koyali and Cochin refineries had not started. When these two refineries and Barauni are completed, total available capacity will just exceed 15 million tons, roughly equivalent to estimated consumption in 1965.

The private refining companies in India have requested permission to expand their plants to meet some of the anticipated consumption increase (beyond 1965), but Government of India has not licensed them to do so. However, at the yearend the Government was considering proposals for minority participation in erection of a refinery in Madras. The Government also approved a proposal of Esso Standard Eastern Co. to establish a 165,000-ton-per-year lubricant plant, using feedstock from the Esso refinery in Bombay. The Government and Esso will be equal partners in a new company which will be organized. Annual demand of lubricants in 1963 was about 275,000 tons, whereas only 30,000 tons per year has been produced at Digboi and 70,000 tons will be produced when Barauni is completed.

India is receiving financial and technical assistance from the U.S.S.R. in the exploration and development of the oilfields of Gujarat and in the construction of the Barauni and Koyali refineries. Out of the US$375 million Soviet credit for third 5-year plan projects of India, US$69.3 million has been allotted for the petroleum industry. Provision for assistance to the industry was also included under the US$125 million supplementary third 5-year plan credit extended in February 1961. A contract was signed between the Oil and Natural Gas Commission and Technoexport, the U.S.S.R. supply organization, for delivery to India of US$18.9 million worth of oil exploration and production equipment. Technoexport will supply six drilling rigs,

Digitized by Google

pipes, and other production, transportation and geophysical equipment.

India also imports petroleum products from the Soviet Union, the quantity envisaged for 1963 was 1 million tons, of which 300,000 tons was to be furnace oil. By the end of the second quarter, 220,000 tons of oil products were imported. This oil was distributed by Indian Oil Co., a Government-owned marketing and distributing company formed in 1959.

Pipelines.—The 756-kilometer, 14-inch pipeline from Gauhati to Barauni, with an annual capacity of 2 million tons, was ready for operation in February 1963. This is the second section of the 1,158-kilometer line (owned by Oil India Ltd.) from Nahorkatiya and Moran fields in Assam to Barauni, the first portion of which, 402 kilometers of 16-inch line, was commissioned in March 1962. The Government-owned Indian Refineries Ltd. signed a contract on July 31 with the Ente Nazionale Idrucarburi of Italy for the construction of two product pipelines, each of 12-inch diameter. One 530-kilometer line will connect Haldea near Calcutta to the Barauni refinery, and the other 680-kilometer line will connect the same refinery to Kanpur in Uttar Pradesh. The foreign exchange cost of the two pipelines (US$11.15 million) will be met out of the US$100 million credit granted by the Italian Government in 1961.

Government Regulations.—For the first time the Government of India extended preferential treatment to products refined from indigenous crude. As of June 1 furnace oil and light diesel oil produced wholly from indigenous crude was exempted from all excise taxes and duties when used in the generation of electricity by the publicly owned electricity undertakings, and in the case of furnace oil, when used in railway locomotion.

The 1963–64 budget leveled exceptionally high taxes on kerosine, high-speed oil, and gasoline.

With the aid of the United Nations Special Fund, an Indian Petroleum Institute was established in Dehra Dun.

The Mineral Industry of Indonesia

By Anton W. T. Wei[1]

INDONESIA's contribution to world mineral supplies is primarily its production of tin and petroleum. Tin output in 1963 accounted for about 6.5 percent of the world's total and ranked the country sixth among world producers. In the same year, Indonesia contributed less than 2 percent to the world's crude petroleum output and ranked 11th among world producers. Indonesia was the largest petroleum producer among the Far Eastern countries but ranked below Malaysia, mainland China, and Thailand in tin production. In previous years, Indonesia's tin production had been considerably greater than that of Thailand.

Domestically, petroleum was by far the most important mineral produced. The 1963 output accounted for nearly 80 percent of the total mineral production value of roughly US$400 million. Tin contributed less than 10 percent, and cement, salt, coal, and bauxite made up most of the balance. Government revenue from minerals in 1963 probably was equivalent to about US$125 million, with roughly 80 percent from petroleum and 10 percent from the tin industry. The contribution of the mineral industry to the gross national product was probably 2 to 3 percent.

Although Indonesia's 1963 overall mineral output was at a lower level than in 1962, activities to expand and diversify the mineral industry continued. Construction and site clearing work for iron and steel facilities was advanced. Most of the construction work on the 25,000-long-ton-per-year tin smelter at Muntok on Bangka Island was completed. In the meantime, all Indonesian tin concentrate, as of November, was being shipped to Arnhem for processing under a smelting contract signed with the Netherlands earlier in the year; formerly, most of the concentrate had been shipped to Malayan smelters.

In September, the government made public a new production-sharing regulation designed to make the concept more attractive to potential foreign investors. Under this concept, repayments of loans by foreign interests are to be made in the form of goods or minerals produced. While confirming that management in principle shall be in Indonesian hands, the new regulation allows for full foreign participation in management if it is deemed essential by the Indonesians. It also provides that equipment, goods, etc., may be imported at the favorable rate of Rp315 to US$1 and that a 5-year tax holiday shall apply to all production-sharing arrangements. Nevertheless, in-

[1] Physical scientist, Division of International Activities.

Digitized by Google

creased economic problems resulting from Indonesia's dispute over the formation of Malaysia and the government's confrontation program have discouraged many foreign companies from making any type of investment in the country.

GOVERNMENT POLICIES AND PROGRAMS

According to Indonesian laws, mineral resources are basically properties of the state, and only a limited number of commodities are exploitable by domestic private interests through negotiation with the government. Foreign interests are permitted to participate in mineral development in Indonesia only on a production-sharing basis. In 1963, petroleum remained the only mineral industry that was not controlled by the government. However, the parliamentary passage on November 9 of petroleum laws governing the operations of foreign oil companies, by far the most significant development in Indonesia's mineral industry during the year, laid down the foundation for the eventual purchase by the government of certain facilities of the oil industry.

SOURCE MATERIAL

Most of the production statistics represent official records carried by the Indonesian Bureau of Mines and supplied to the U.S. Embassy. Data on trade were obtained from official government returns. Information on mineral activities came mainly from Embassy dispatches; the most important of these is the annual minerals report for 1963.

PRODUCTION

Increases in the production of bauxite and coal during 1963 were more than offset by decreases in tin and petroleum output. Indonesia's tin output showed the sharpest decline since World War II as production of concentrates dropped almost 34 percent [2] from the 1962 level. This represented a little more than a third of the postwar peak level achieved in 1954 and roughly half the 1958–60 rate, when export controls were enforced under the International Tin Agreement. Moreover, for the first time in recent history, Indonesian tin production fell below that of Thailand. The country's crude petroleum output, on the other hand, declined only slightly from an average of 457,800 barrels per day in 1962 to 445,200 barrels in 1963.

In contrast to the reductions in tin and petroleum output, the production of bauxite from Bintan and adjoining islands increased by over 6.9 percent (nearly 32,000 metric tons) in 1963. The 1963 bauxite output, however, was nearly 7,000 tons short of the Indonesian Government target of 500,000 metric tons. Similarly, coal production in 1963 increased more than 120,000 metric tons over that of 1962, but fell 59,000 tons short of the government target of 650,000 tons.

[1] Final figure; supersedes figure given in commodity chapter, vol. I.
[2] Officially reported Indonesian statistics representing government output; private production, by small unorganized producers, may be as much as 30,000 troy ounces per year.
[3] Data not available.
[4] Reported output, believed to represent mainly, if not entirely, export shipments from wartime stocks.
[5] Estimate.
[6] Breakdown reported for 1961, in thousand barrels, as follows: Gasoline 18,215, kerosine 14,766, distillate fuel oil 18,883, residue fuel oil 26,168, and other 1,810.

TRADE

Most of Indonesia's mineral commodities are exported; the total represents nearly 90 percent by weight and more than a third by value of all Indonesian exports. Mineral exports in 1963 showed a decline from the 1962 rate because of reduced shipments of petroleum and tin. These two commodities have accounted for 95 percent or more of the country's annual exports of mineral commodities. The reduced tin export followed the downward production trend, but the marked decline in the production and export of refined petroleum products was due to the Indonesian Government's intensification of its economic offensive against Malaysia. Although exports of crude oil were up slightly, from an average of 251,200 barrels per day in 1962 to 257,400 barrels for 1963, average daily exports of refined products fell from 123,800 barrels in 1962 to 107,500 barrels in 1963. Definitive 1963 trade data on bauxite, the only other Indonesian mineral export of some significance, are not yet available. However, in line with the increase in production, total shipments, all to Japan, probably were at a slightly higher rate than in 1962.

COMMODITY REVIEW

METALS

Gold and Silver.—The Indonesian Department of Basic Industries and Mining announced in 1963 that it had contracted for the construction of an electric power plant and power lines to an abandoned dredge at the nonoperating Logas gold mine in Riau Province. The department hoped that mining operations at Logas would resume in 1964. The Logas deposit has been estimated as being capable of producing the equivalent of 200 to 300 kilograms of gold per year.

In the meantime, the government-owned company, P.T. Tambang Mas Tjikotok, with mines at Tjikotok and nearby Tjirotan in West Java, remained the only gold-and silver-mining operation officially in existence during 1963. However, many unofficial small-scale opera-

Digitized by Google

tions known as "people mining" were active and probably produced more precious metals than the official operation.

Iron and Steel.—Construction continued on the Soviet-financed steel mill at Tjilegon in West Java. This 100,000-ton-per-year steel plant and rolling mill has no iron-smelting facilities and initially will use domestic scrap and imported pig iron as raw materials.

The search for iron ore and coking coal for the establishment of an integrated iron and steel industry was continued throughout 1963 by a team of Soviet technicians in Kalimantan, but information from Indonesian Government sources indicates no discovery of any significance. In the meantime, it was reported that core drilling of iron deposits in the Lampung area of South Sumatra by engineers of the Directorate of Geology delineated only 300,000 tons of ore instead of the 10 million tons estimated previously. It has been reported that the blast furnace facilities, to be erected in the area with financing from West Germany, will have to depend on iron sands from south Java as part of the raw materials. At yearend, actual construction had not begun, although land clearing had started at the project site.

Manganese.—The Manganese Mining Co. at Kliripan, Special District of Jogjakarta (central Java), formerly a privately operated company, was taken over by the Special District government. Thirty million rupiahs worth of equipment was purchased from Japan to renovate the mine. Meanwhile, mining operations on Java were dormant during most of 1963 because of lack of markets. Stockpiled ore on the island was reported to be 30,000 tons near yearend. Japanese interests continued to be the only purchasers of Indonesian manganese.

Nickel.—Negotiations between the Japanese Sulawesi Nickel Resources Development Cooperation Co., the General Management Board of (Indonesian) State Mining Enterprises, and P.T. Nickel (a privately owned Indonesian company), which began in 1961 and continued through 1962, were successfully concluded in 1963. A final series of negotiations in Tokyo resulted in the signing of a production-sharing contract in which Japan agreed to provide credits equivalent to US$1.35 million in the form of mining equipment and technical services. Repayment of the loan is to be made in nickel over a 7 year period. Production was to begin in mid-1964 and the near-future target is 16,000 tons of ore per month, 6,000 tons from Mantang Island and 10,000 tons from Pomalaa on the mainland of southeast Sulawesi. The nickel content of the ore averages about 3 percent.

Tin.—Although most of the construction on the Peltim smelter at Muntok, Bangka Island, was completed during 1963, work on harbor and related facilities continued into 1964. Officials of the Indonesian Tin Bureau expected the smelter to go into full production in mid-1965. In the meantime, the smelting contract with the Arnhem smelter of the Netherlands, signed in early 1963, contains a clause allowing for cancellation when Peltim goes into full production.

A formal application for a development loan of US$12 million was submitted to the U.S. Agency for International Development (AID) during June 1963 by the Indonesian General Management Board (Badan Pimpinan Umum—BPU) for State Tin Mining Enterprises (Perusahaan Tambang Timah Negara—TIMAH). The tin project contemplated under the terms of the loan application conformed

Digitized by Google

with recommendations of the Colorado School of Mines Research Foundation contained in its report dated October 1962. It was conceded by both United States and Indonesian officials that approval of the loan would depend on acceptance by the Indonesian Government of a plan sponsored by the United States and several European countries to stabilize the economy; the application was pending at yearend.

Indonesia was paying increasingly more attention to the offshore mining of tin as known land reserves on the tin islands are limited. BPU–TIMAH signed a contract in 1963 with the United Kingdom firms of Simon-Lobnitz and Alexander Stephen and Sons, Ltd., for the construction of a large deep sea dredge capable of producing 1,000 tons of mine tin per year; 80 percent of the contract price was financed with a loan of £2,240,000 from United Kingdom banks. Completion of design and construction of the dredge would take 3 years.

MINERAL FUELS

Coal.—The increase in coal production in 1963 reversed the downward trend of the past several years. The Bukit Asam open pit operation in South Sumatra has always been Indonesia's largest coal producer. The Paul Weir Co. of Chicago, in its report of 1963 based on its feasibility study conducted in late 1962 under AID sponsorship, proposed a 4-year program with moderate expenditure to increase annual production of Bukit Asam to 700,000 tons of coal. Meanwhile, large-scale improvements would be made, so that the mine would be equipped and organized to go on to an annual output of 2 million tons within 3 additional years. The cost of this overall project was estimated at US$11.7 million, US$10.5 million for equipment and US$1.2 million for engineering and technical services. Through yearend BPU had made no application to AID for a development loan, as had been intended originally.

The Ombilin underground mine in west Sumatra was being converted into a modern mechanized operation with credits, equipment, and technicians provided by the Government of Poland. The project calls for an eventual annual output of 1 million tons. The Mahakam Coal Mine is the official name given to the State enterprise in east Kalimantan, often referred to by such place names as Samarinda, Laokula, and Sebuku. Production from this small operation using crude methods will not become important unless large-scale modernization is undertaken.

Petroleum.—The Indonesian petroleum industry passed one of its major milestones in 1963 when the government enacted two laws on November 9 which approved working agreements between the State-owned oil companies and foreign interests operating in the country. The first, and by far the more important, approved contracts signed on September 25, 1963, between the Indonesian Oil Mining Co. (Pertambangan Minjak Indonesia—Pertamin) and the Caltex Pacific Oil Co., between National Oil and Natural Gas Mining (Pertambangan Minjak dan Gas Bumi Nasional-Permigan) and P.T. Shell Indonesia, and between National Oil Enterprise, Ltd. (P.T. Perushaan Minjak Nasional-Permina), and P.T. Stanvac Indonesia. Under the terms of the contracts, these established foreign oil companies agreed to give up

Digitized by Google

all rights held prior to the 1960 Minerals Law and to become contractors to the Indonesian State companies. The second law approved the agreement reached between Pertamin and the Pan American Oil Co. in June 1962, when the latter first ventured into Indonesia for the purpose of oil exploration work.

Upon signing the contract, each company agreed to pay US$5 million as an initial bonus; the companies also will pay the government 60 percent of their net profits calculated on actual earnings, the same rate that had been applicable during the previous 2 years. These oil companies are to sell all domestic marketing facilities to the Indonesian Government within the next 5 years. Shell and Stanvac were guaranteed retention of their refineries for 10 years, but provision was made for the sale of these facilities to the Indonesian Government before the end of 15 years, with the sale price decreasing to zero if the transaction is made at the end of the period. The companies' exploitation rights on existing producing areas are to extend for 20 years. Perhaps most significant to the future of Indonesia's petroleum industry is the provision for the companies to explore in extensive new areas in Kalimantan and Sumatra for a maximum of 30 years.

The Mineral Industry of Japan[1]

By K. P. Wang[2]

JAPAN'S mineral industry ranked about sixth or seventh in the world in 1963. Its estimated mineral and metal output value (mine output value plus added value derived from smelting and processing) in 1963 was approximately US$4.5 billion, about equal to that of France and substantially more than that of mainland China. The mining industry was only of moderate significance. However, the metallurgical industry was very large and diversified to meet the demands of the Japanese industrial-manufacturing economy.

While Japan's mineral resource base has proven stronger than it was generally suspected in the past, raw material requirements have far exceeded domestic supplies of most commodities, necessitating large imports from many parts of the world. Possessing an advanced technology, the country processed various crude ores into finished mineral and metal products partly or primarily for export. To meet domestic and foreign demand, many mineral commodities were produced in world significant quantities during 1963.

The country ranked fourth behind the United States, the Soviet Union, and West Germany in output of steel, and the annual steel production rate in late 1963 indicated that Japan could surpass West Germany in 1964. Japan was a significant world producer of nonferrous base metals, being more prominent in zinc and copper than lead. Aluminum production rose; Japan ranked fifth in the world in its production. The country remained second in titanium production behind the United States. Japan was also a prominent producer of ferroalloys, minor metals, and high-purity metals. Among nonmetal mineral products, Japan ranked first in the world in pyrite output, third in cement production (which increased sufficiently to maintain this position) behind the United States and the U.S.S.R., and either first or second in pyrophyllite output. In mineral fuel commodities, Japan was an important refiner and consumer of crude oil and produced sizeable quantities of coal. Japanese output of many additional mineral commodities constituted 1 to 2 percent of the world totals.

Steel, Japan's premium industry, experienced growth in many directions during 1963. All of the large steel companies were either building new steel centers or adding new facilities to existing centers. Technical improvements were made, particularly with regard to intensifying blast furnace smelting and streamlining oxygen converter

Commodity	Approximate world rank in output	Approximate share of world output (percent)	Adequacy of production	Raw material supply [1]
Metals: [2]				
Aluminum (smelter).	5	4	Roughly self-sufficient.	Virtually all bauxite imported.
Bismuth	About 5	10	Moderate surplus	Byproduct of nonferrous ores.
Cadmium	5	8	Large surplus	Mostly domestic zinc byproduct.
Copper (smelter)	8	5	Somewhat deficient	Ore imports exceed output.
Iron, pig	4	7	Slightly deficient	About 85 percent iron ore imported.
Iron, steel ingot	4	8	Self-sufficient	Nearly one-fourth metallic iron imported.
Iron, steel products	4	About 8	Sizable surplus	Virtually all steel ingot used is made locally.
Lead	8	4	Somewhat deficient	Ore imports nearly equaled output.
Magnesium	7	2	Slightly deficient	Raw material is local dolomite.
Manganese ore	10	2	Greatly deficient	All high grade ores imported.
Mercury (mine)	8	2	do	Ore imports 4 times mine output.
Nickel (smelter)	Among first 10.	Under 2	Somewhat deficient	All nickel ores imported.
Tin (smelter)	11 [1]	1	Greatly deficient	Ore imports nearly twice.
Titanium [3]	2	20	Large surplus	Mostly domestic titaniferous sands.
Zinc (smelter)	3	About 8	Slightly deficient	About one-fourth ore imported.
Nonmetals:				
Cement	3	About 8	Small surplus	Predominantly domestic; some gypsum imported.
Feldspar	7	3	Self-sufficient	Almost all domestic.
Pyrite	1	20	do	All domestic.
Pyrophyllite	1 or 2	23	do	Domestic pyrophyllite clays.
Sulfur	6	2	do	Domestic sulfur-pyrite ores.
Mineral fuels:				
Coal	10	2	Great shortage of coking coal.	Steam coal reserves can sustain output.
Coke	5	5	Nearly self-sufficient	Most good coking coal imported.
Refined petroleum	About 5	About 4	Self-sufficient except fuel oil.	More than 98 percent crude oil imported.

[1] Estimate.
[2] Japan produced and exported large quantities of ferroalloys, based mainly upon imported ores. It also produced great varieties and sizable tonnages of lesser and minor metals.
[3] Status pertains to the free world countries only, with the Soviet Union excluded.

operations. In the nonferrous base metals industry the most noteworthy developments were Mitsubishi Metal's decision to build a very large and modern copper refinery and the start of aluminum production by a fourth company, Mitsubishi Chemical, which processed alumina imported from Australia. A number of giant-sized cement kilns were installed in 1963. Japan experienced its worst coal mine disaster at Mitsui Coal Mining's Miike mine—the country's foremost coal mine. Hydraulic coal mining was being encouraged. The oil refining industry greatly expanded, with additional refining capacity being built. At yearend, it became increasingly apparent that crude oil production from Japan's concession in the Kuwait-Saudi Arabia Neutral Zone showed great promise.

GOVERNMENT POLICIES AND PROGRAMS

The Japanese Government continued in 1963 to pursue the policy of maximum development of domestic resources and importation of de-

Digitized by Google

ficient items as required. With Japanese industry operating under the private enterprise system, the Government exercised its regulatory functions only to a moderate extent while carrying out definite mineral policies.

Government programs included giving assistance to small mines in 1963 through favorable taxation and aid in exploration. Large mining companies were able to benefit from this assistance also by placing marginal and new operations into the status of small subsidiaries. The program of rationalization was emphasized, involving closure of uneconomic mines, consolidation of operations, erection of new shafts, and technical improvements in general. Japanese mines were being readied for more open world competition under the trade liberalization program and through the reduction of foreign exchange restrictions. The coal industry was still protected in 1963, but the policy was to rely on imported petroleum to meet most of the expanding energy needs.

The government exerted considerable influence on mineral and metal imports through foreign exchange controls, import quotas and duties, and direct and indirect financing. Private Japanese companies were urged to present a united front abroad in developing and purchasing minerals. The policy has been to spread raw material imports in as many areas as possible to insure dependability of supply and balanced trade with various countries. An ore carrier construction program to reduce shipping charges from distant lands has been in existence for some years. The quasi-government Overseas Mineral Resources Development Co. was formed in 1963 to help develop some of the more risky mines abroad.

In the case of metallurgical and refining facilities, which process both indigenous and imported raw materials, the role of the government has been to encourage rationalization and modernization, promote establishment of new facilities according to need, pass judgment on important large projects, allocate production quotas among individual companies, and help hold back construction programs in times of economic stress. Better conditions in 1963 as compared with conditions in 1962 brought about more liberal policies towards development of additional plant capacity.

Japanese laws have been designed to attract foreign investment, loans, and technical assistance. The Foreign Investment Law of Japan, applicable to all firms, does not prohibit majority stock ownership by foreign concerns, although in practice Japanese capital almost always prevails. As of 1963, foreign capital (particularly U.S. capital) was involved heavily in the oil, aluminum, and mining equipment industries. On the other hand, the steel industry, which used foreign loans and technical licensing arrangements to accelerate development, was solidly in Japanese hands. Most large nonferrous base metal concerns were also predominantly financed by Japanese capital, but recently a few have joined with foreign capital in developing mineral deposits abroad. The Japanese Government held the power of approval over specific projects involving foreign participation.

PRODUCTION

Japan's overall mineral output value in 1963 was more than 10 percent higher than that in 1962. Progress during 1959–63 was even more striking, with a total increase well over 50 percent. Production based upon domestic mineral raw materials rose at a far lesser pace than that based upon imported raw materials. The large and modern metallurgical industry, exemplified by the steel sector which relied primarily on foreign iron ore and scrap, has expanded greatly in the last 5 years.

The Mining Yearbook of Japan, published annually by the Ministry of International Trade and Industry (MITI) and containing fairly accurate statistics, gives only a partial picture of the country's mineral output value. For 1962 (the last year available) US$1.882 billion was credited as the output value. By adding major omitted items, such as the estimated added values derived from domestic raw material-based cement and steel and imported raw material-based steel, nonferrous metals, and oil, the actual total would exceed US$4 billion for 1962. The US$4.5 billion dollar estimate made for 1963 constituted about 7.5 percent of the gross national product (GNP for fiscal year 1963 was about US$61 billion).

TABLE 2.—Reported value of selected mineral products, 1962[1]

(Million U.S. dollars)

Commodity group	Output value	Added value	Total
Metal ores	178	118	296
Nonmetal ores	103	64	167
Metals other than iron	386	52	438
Coal	562	362	924
Oil and gas	36	21	57
Total	1,265	617	1,882

[1] Includes only items produced from domestic raw materials and does not include added value derived from domestically based cement, iron and steel. The figures also exclude very sizable mineral output values derived from processing imported raw materials such as ferrous and nonferrous ores and crude oil.

Steel, chiefly as a result of added value through processing imported raw materials, accounted for about 33 percent of the 1963 mineral output value; domestic coal, about 20 percent; oil refining, about 12 percent; added value for metals produced from domestic ores, about 10 percent; domestic metal ores, about 7 percent; added value in processing imported nonferrous ores about 3 percent; cement, about 7 percent; and other nonmetals, about 4 percent.

Production of specific mineral products clearly reflects the overall expanding nature of the economy, in terms of greater and more diversified internal demand, general success in acquiring foreign raw materials and selling finished products abroad, mass construction of new production facilities, and improved efficiency in operations and maximum utilization of available resources. Although the general tendency was upwards, output was affected by Japanese and worldwide economic cycles which, for example, showed that 1962 was a recession year and 1963 a year of recovery and renewed expansion.

During 1959–63, output of steel, aluminum, and cement approximately doubled, there being a steady demand for these products in

Digitized by Google

construction and no raw material shortages. Because of cost difficulties and competition from oil, coal production increased only slightly from 1959 to 1962 and fell in 1963 by over 2.5 million tons nearly to the 1960 level. Petroleum refining and consumption showed a phenomenal rise, with oil furnishing about half of the 1963 energy supply. In nonferrous base metals, mine production rose slightly during 1959–63, whereas metal production increased by more than 50 percent. Some special metals and alloys, which are depended upon the foreign market to an important extent, fluctuated mildly while others declined. Output of many minor metals increased. Almost all of the nonmetals showed production increases. A very notable trend in 1959–63 was that Japan's overall mineral consumption had risen radically.

By yearend 1963 Japan was producing at an annual rate of 35 million tons of steel, 30 million tons of cement, and over 50 million tons of both refined oil and coal. Among the lesser but still important mineral products, the country was also producing roughly 1 million tons of nonferrous metals, 500,000 tons of ferroalloys, and a total of 3 million tons of various kinds of pyrites.

TRADE

Japan has been an important world trader of mineral raw materials and products, being both prominent as an importer and an exporter. Among the major items imported during 1963 were more than 26 million tons of iron ore, over 4 million tons of steel scrap, nearly 10 million tons of coking coal, just under 52 million tons of crude oil, 1.4 million tons of bauxite, nearly 300,000 tons of copper, almost 150,000 tons of combined lead-zinc in terms of ore content, over 300,000 tons of manganese ore, nearly 250,000 tons of chromite, roughly 1 million tons of potash, 2 million tons of phosphate rock, and 3 million tons of salt. Japan's mineral imports were not only important by world standards but also represented a significant share of the country's overall imports, roughly 30 percent of the total value.

Steel semimanufactures represented by far the leading class of Japanese mineral and metal exports, and the country was one of the world's foremost exporters of such products. This class alone, comprising over 5 million tons in aggregate weight and valued at more than US$700 million in 1963, constituted one-seventh of Japan's total exports. Large quantities of additional steel were exported in the form of finished products. Japan's 2 million tons of cement exports in 1963 also loomed large by world standards, although valued at only some US$30 million. Many other mineral products were exported in lesser amounts. Generally, mineral exports were not as important as min-

Digitized by Google

eral imports, since Japan's economy places much greater stress on exports of manufactured products.

The United States was Japan's most important single mineral trading partner, furnishing nearly one-third of the imports and taking more than one-fourth of the exports. American coking coal, steel scrap, molybdenum concentrate, and phosphate rock represented well over one-half of Japan's imports of such items during 1963. In return, the United States took about 30 percent of Japanese iron and steel exports. The Near East provided four-fifths of Japan's crude oil imports, including an important share from Japanese concessions in the Kuwait-Saudi Arabia Neutral Zone. Malaya (subsequently Malaysia) was the leading source of iron ore, followed by India. The Philippines, Australia, and Canada were the prominent suppliers of nonferrous base metals (mostly in concentrate form). Although emphasis has been placed on closer areas, such as Southeast Asia, South Asia, and Australia, Japan continued to draw mineral supplies from all over the world. Japanese steel products were likewise shipped to many parts of the world, with significant shares going to the United States and to less developed Far East countries. The principal foreign markets for Japanese cement were within the Far East.

TABLE 4.—Mineral trade with the United States in 1963 [1]

Item	Total (million U.S. dollars)	U.S. share of total (percent)	Item	Total (million U.S. dollars)	U.S. share of total (percent)

Coal	180.9	53.8			

[1] Selected major items only.

As one result of the worldwide quest for mineral raw materials, Japan encountered both domestic and international pressures to liberalize import regulations. Specific mineral and other products were controlled in terms of foreign exchange allocation and import quotas, and tariffs were set up to protect domestic industry. Although the Japanese concept of "liberalization" was to reduce restrictions and permit more open competition, duties were in some cases temporarily increased. Crude oil import controls were liberalized in October 1962 and those of copper in April 1963. At the end of 1963, lead and zinc import regulations were due to be liberalized. A new era was beginning for Japan in international trade as a result of the gradual liberalization of imports in minerals and other products.

COMMODITY REVIEW

METALS

Iron and Steel.[3]—Japan's steel production in 1963 reached a new high, putting the country in a virtual third place tie with West Germany behind the United States and the U.S.S.R. Oxygen converter steel rivaled open-hearth steel for the first time, and is due to take over

[3] Far East Iron & Steel Trade Reports (Tokyo). No. 110, Mar. 12, 1964, pp. 1–20.

Digitized by Google

the leading position shortly because most additional steel capacity being built is of this type. Pig iron production was slightly under 20 million tons. Output of 2.46 million tons of alloy steels made Japan the third largest world producer in this category. Statistics for the last quarter of 1963 and new facilities recently placed in operation show that the upward trend in both steel and pig iron output can be expected to continue.

During 1963, Japan imported about 22 million tons of iron, nearly three-fourths contained in iron ore, one-fifth in scrap, and the rest in pig iron. Special ore carriers enabled the country to acquire raw materials cheaply from distant sources. About 55 percent of the iron ore came from nearby Asian countries, with Malaya ranking ahead of all other suppliers; two-thirds of the scrap came from the United States. While imports of iron materials rose one-fourth over those of 1962, imports of coking coal, mainly from the United States and Australia, remained at roughly the same level. Foreign purchases of coking coal were held down in 1963, partly because of reduced coke requirements per ton of iron produced in blast furnaces and greater use of inferior quality domestic coking coals.

Of Japan's total 1963 semifabricated steel output (including special steels), roughly 21 percent valued at some US$760 million was exported. While domestic demand rose markedly, the 30-percent increase in steel exports over 1962 steel exports made Japan a very prominent world exporter of steel. Direct exports of steel products in 1963 were equivalent to 7 million tons of crude steel, and indirect exports contained in finished products like ships and automobiles amounted to another 3 million tons of crude steel. The trend was toward indirect exports beyond the 1963 level. Overall, Japan imported about one-third of the iron materials needed for steel manufacture in 1963 and exported nearly one-third of the steel as steel and other finished products, emphasizing the indispensable role of iron and steel trade.

Japan, with the largest oxygen steel converter capacity in the world, has strengthened its competitive position by adopting the most advanced steelmaking techniques. In 1963, efforts were directed toward technologic improvement in ore mixing, sizing, sintering, and pelletizing as well as toward increasing automation. Injection of heavy oil, such as done at Yawata Iron & Steel Co., Ltd's. No. 3 furnace at Tobata, was employed in at least 28 blast furnaces, with the oil volume per ton of pig iron produced raised to 13 to 18 gallons, compared with 8 to 13 gallons in 1962. High-pressure operations were initiated at three blast furnaces, and Fuji Iron & Steel Co., Ltd's. No. 3 furnace at Muroran achieved the record pig iron tapping ratio of 2.05 metric tons per cubic meter of hearth volume. Average Japanese coke ratio was lowered 10 percent to not much more than 500 kilograms per ton of pig iron produced by these practices coupled with greater use of sintered ore.

As of September 1963, there were 29 LD (Linz Donawitz) top blown ogygen converters of 40- to 150-ton size operating in Japan. Most converters produced above rated capacity; some were computer controlled. Improvements were made in oxygen generators and converter waste gas recovery. Yawata Iron & Steel Co., Ltd. and Yoko-

Digitized by Google

yama Engineering Co., Ltd. jointly developed a waste gas recovery technique known as the O.G. process, which was successfully applied in Japan and licensed for use by West German firms. A new iron sand electric smelting technique known as the E.K. process was jointly developed by Nisso Steel Mfg. Co., Ltd. and Electrochemisk of Norway. This technique is capable of cutting power requirements and overall costs by 15 percent.

Four small-scale special steel companies were employing continuous casting, and large producers of ordinary steel were studying the technique for inclusion in major new steelworks being built or planned. A contract was reportedly signed on October 23, 1963 between Kobel Steel Works, Ltd. on behalf of the Japanese steel industry and Moscow for the rights to adopt a Soviet continuous casting method that would do away with many heating pits and moulds and eliminate blooming and slabbing mills altogether. In rolling, multistand hot strip mills with automatic thickness gages and loop controlling devices started operations in 1963, and a plan was conceived for computer control of the entire strip mill process.

The big six steel companies, headed by Yawata Steel and Fuji Steel and each with one or more large new projects, continued to dominate the Japanese steel industry, providing about 90 percent of the pig iron and two-thirds of the crude steel in 1963.

Yawata Steel's Tobata Works was fully completed, the Kisarazu Works passed beyond the planning stage, and construction of a mammoth blast furnace and two converters at Yawata Steel's Sakai Works was resumed at yearend. Fuji Steel's new project is the Nagoya Works of its subsidiary Tokai Iron & Steel Co., Ltd.; a hot strip mill, a cold strip mill, and a Sendzimir continuous galvanizing line were already in operation there in 1963, and the first of five large blast furnaces was expected to be blown in by September 1964. Nippon Kokan Kabushiki Kaisha (Nippon Steel Tube Co., Ltd.) started first-stage construction on its Fukuyama Works, after reclaiming the necessary land site from the sea in November 1963. Kawasaki Steel Corp. completed its second large cold strip mill at the Chiba Works in mid-1963 and was working hard on building the fourth blast furnace at this site. Sumitomo Metal Industries, Ltd. blew in the second of five proposed large blast furnaces at the Wakayama Works in April 1963.

Ferroalloys, Ferroalloy Metals and Their Ores.—Japan retained its prominent world position in the production of ferrous metals for

TABLE 7.—Approximate annual output rate of major steel firms during the third and fourth quarters 1963

(Million metric tons)

Firm	Pig iron		Crude steel	
	Third quarter	Fourth quarter	Third quarter	Fourth quarter
Yawata Steel	5.3	5.5	6.3	6.5
Fuji Steel	4.8	5.2	5.2	5.6
Nippon Kokan	2.7	2.9	2.9	3.6
Kawasaki Steel	2.2	2.5	2.7	3.5
Sumitomo Metal	1.8	2.2	2.7	3.1
Kobe Steel	1.0	1.0	1.6	1.6

Digitized by Google

alloying during 1963, with total output of ferroalloys at about 500,000 metric tons, up 33,000 tons over that of 1962. Although increased steel production raised demand for ferroalloys, the Japanese ferroalloy industry comprising about 45 producing firms was beset by difficulties. Much capacity, some obsolete, remained unused. The export market had dwindled to about 27,000 tons and the steel industry was abandoning its paternalistic purchasing policy in ferroalloys. Increasing power costs and liberalization of ferroalloy imports were squeezing the less efficient operations out of business. Some large plants such as the Shimminato Works of Nippon Kokan and certain specialized plants were able to compete effectively. However, merger of companies was generally looked upon as a method to streamline the industry. In September 1963, Toho Denka K.K. and Nippon Denki Yakin (Nippon Electric Metallurgical Co., Ltd.)—two of Japan's leading ferroalloy producers—announced plans to merge in 1964.

The raw materials base for supporting the Japanese ferroalloy industry remained very weak. All the high-grade and metallurgical-grade chromite and manganese ore required had to be imported. Japan was dependent upon Climax Molybdenum for most of its molybdenum concentrate imported, and demand was expected to rise to 5,000 tons annually in the near future; Canada Explorations was scheduled to make its first shipment of molybdenum concentrate to Japan in August 1965. Tungsten concentrate imports were four times production, but the concentrate was inexpensive and easily available. All nickel ore was imported, the bulk from New Caledonia. The United States was the only important source of vanadium concentrate.

The same Japanese firms producing ferroalloys also produced pure ferrous metals. Tekkosha K.K. occupied a commanding position in diversity as well as total tonnage in 1963, being the sole important producer of electrolytic manganese and chromium in Japan. Sumitomo Metal Mining Co., Ltd. and Shimura Kako (Shimura Chemical Industry Co., Ltd.) were the only two nickel producers; and Mitsubishi Metal Mining Co., Ltd., Tokyo Tungsten Co., Ltd, and Tokyo Shibaura Denki (Tokyo Shibaura Electric Co., Ltd.) controlled the metallic tungsten and molybdenum business. Most of the chromium and one-half of the manganese were exported. There was a small surplus of metallic tungsten and molybdenum, whereas all of the nickel was domestically consumed. During 1963, Japan produced 6,190 tons of nickel, 515 tons of tungsten, roughly 400 to 500 tons of chromium, 4,000 to 5,000 tons of manganese, and over 100 tons of molybdenum.

Nonferrous Metals.[4]—Japan's nonferrous metals industry, which with the exception of aluminum has a much stronger raw material base than the steel industry, experienced the same general growth as steel in 1963. However, world significance of the country's copper, lead-zinc, and aluminum industries was less than that of steel. Japan has had to purchase nonferrous raw materials from many parts of the world to meet smelter requirements and domestic consumption. In 1963, nonferrous imports totaled nearly US$250 or roughly two-fifths the smelter value. Aluminum production was based entirely on imported raw materials, but output of copper, lead, and zinc came in part from domestic mines which still provide an important though decreasing

[4] Japan Metal Bulletin (three times weekly) 1963–64. The Sangyo Press, Ltd., Osaka.

Digitized by Google

share of the total ore supply. The protected base metals mining industry was being readied for more open world competition during 1963, with copper imports liberalized in April and lead-zinc imports to be liberalized in early 1964.

Aluminum.—The one-third rise in aluminum output in 1963 was brought about by vastly increased demand, expanded capacity at existing plants, and commencement of operations by the Chiba plant of Showa Denko near Tokyo and the Naoetsu plant of Mitsubishi Chemical Industries Co., Ltd. in northern Nigata. The 30,000-ton-per-year Naoetsu plant, that began production in September 1963, used Australian alumina exclusively. At yearend, annual capacities for the other three companies were as follows: Nippon or Japan Light Metal Co., Ltd., 110,000 tons; Showa Denko K.K., 80,000 tons; and Sumitomo Chemical Industries Co., Ltd., 60,000 tons. A new 7,500-ton-per-year plant belonging to Sumitomo Chemical was nearing completion. Japan's newest and best reduction pot lines consume 16,000 kilowatt-hours per metric ton and have fluorine recovery and gas shield systems. Should ALCAN's Arvida Works be successful, Nippon Light Metal which is affiliated with ALCAN, expects to install a 10,000-ton-per-year direct reduction plant in 1966 or 1967.

Copper, Lead and Zinc.—The trend toward greater imports of copper, lead, and zinc to meet rising demand continued in 1963. However, Japanese mining firms, which built their business initially on local ores, retained control of the overall raw materials supply and smelting activities. The Sumitomo enterprise founded on the Besshi copper mine, the Mitsui enterprise on the Kamioka lead-zinc mine, and the Nippon mining enterprise on the Hitachi copper mine, together with a few other firms not only managed the major domestic nonferrous mines and the much larger smelters but also various projects abroad.

The most important developments in mining during 1963 took place in the field of the metallurgically difficult-to-treat complex "kuroko", or black ores, of northern Honshu, Japan. These ores, found in three subzones of varied composition and sometimes associated with recoverable gypsum, can average 2 to 3 percent copper, 5 to 20 percent combined lead-zinc, and much silver. In 1963, Dowa Mining Co., Ltd. was developing a very modern mine-mill plant based upon the 9.3-million-ton Uchinotai ore deposit; Nippon Mining Co., Ltd. delineated 1-million-ton ore reserve at Shakanai, with prospects for finding much more ore, and started to sink a shaft; Mitsubishi Metal Mining Co., Ltd. was readying the 2.5- to 3-million-ton Furutobi ore deposit for production. These and other finds can only add some 10,000 tons of mine copper and corresponding amounts of lead-zinc annually to the Japanese supply.

Foreign raw materials played a much more significant role. Emphasis was placed on acquiring dependable long-term suppliers, primarily of concentrates but also of ingot and scrap. Many mines abroad were developed with Japanese aid. Nippon Mining contracted to import half the copper output of Marinduque, Philippines, for the next decade. Sumitomo Metal Mining Co., Ltd. received the first shipments of Bethlehem copper ore from Vancouver. Mitsubishi Metal and Mitsui Mining & Smelting Co., Ltd. continued to import

Digitized by Google

virtually all the copper concentrate produced at Toledo and Sipalay in the Philippines, respectively. Dowa Mining was helping to develop copper deposits at Whim Creek, Australia, and Santa Rosa, Chile; and Nitto Mining Co., Ltd. completed a copper mill at Chacarilla near La Paz, Bolivia. The Overseas Mineral Resources Development Co. was involved with the Chapi copper mine in Peru and Matilde lead-zinc mine in Bolivia. The Japanese also purchased concentrates and metals from established mines, including lead and zinc from Broken Hill and Mount Isa, Australia, and zinc concentrate from Bawdwin, Burma and Aguilar, Argentina.

Japan's nonferrous smelting facilities have undergone steady modernization and expansion to process both domestic and imported ores. At yearend, total annual capacities were approximately 370,000 metric tons of electrolytic copper, 120,000 tons of refined lead (85 percent electrolytic and the rest Parkes) and 340,000 tons of refined zinc (62 percent electrolytic and the rest distilled). Nippon Mining still led the copper refineries, but Mitsubishi Metal and Mitsui Smelting in particular were moving up. Mitsui Smelting retained its dominant position in lead-zinc, followed by Mitsubishi Metal, Toho Zinc, and Nippon Mining.

The most important nonferrous smelting development in 1963 concerned Mitsubishi Metal's decision to build a 60,000-ton-per-year copper refinery at Onahama in Fukushima north of Tokyo for completion by September 1965, to cut costs by 20 percent, and replace the firms less efficient capacity. Mitsubishi already has a large new zinc refinery with fluosolid reactors at Akita in the north, where annual capacity was recently expanded to 42,000 tons. Toho Zinc's Annaka zinc refinery was expanded one-sixth to 64,800 tons per year in mid-1963. Mitsui Smelting added 4 new vertical zinc retorts to the existing 12 at Miike, raising capacity to 28,800 tons yearly. Nippon Mining further improved its direct reduction converter copper plant at Hitachi and, through its subsidiary Nippon Seiren Co., Ltd., completed an electrothermic zinc unit to the already large Middaichi zinc refinery.

Titanium and Magnesium.—The Japanese titanium industry, long producing below one-half capacity, was preparing to raise output above the 1,759-ton level registered in 1963. Osaka Titanium Co., Ltd., which operated 6 of 10 furnaces, planned to place 2 more in production. Toho Titanium Co., Ltd. was the only other producer of sponge. Much work was done by Kobe Steel in titanium fabrication to promote domestic consumption and relieve dependence on the U.S. market for sales.

The titanium industry in employing the Kroll Process helped the magnesium industry to get started again. Furukawa Magnesium Co., Ltd., the lone Japanese producer of the metal, in foreseeing expanding markets in aluminum alloying, titanium smelting, and ductile iron casting, planned to raise annual capacity from 3,000 to 5,000 tons. Dolomite was used as the raw material for making magnesium, and 19 furnace units with 304 retorts were operated by Furukawa in 1963.

Lesser and Minor Metals.—Japan, to meet the demands of its advanced industrial economy, produced and/or consumed a great variety and sizable tonnages of lesser and minor metals in 1963. Many such

Digitized by Google

metals were byproducts of smelting, and quite a few were mainly supported by indigenous raw materials. Some have been discussed under "Ferrous Metals," although the purified metals were not necessarily used in steelmaking. The Japanese also produced a number of superpure metals. Lesser metals important by world standards include bismuth, cadmium, mercury, and selenium, with Japan producing 8 to 15 percent of the world total in each case.

Bismuth was extracted at lead and copper smelters, mainly by Sumitomo Metal & Mitsui Smelting. At yearend, Sumitomo Metal contracted to sell most of its monthly output of 14 tons to the United Kingdom, whereas the other firms sold to the domestic market. Cadmium was produced at the zinc refineries, primarily from domestic ores; most of the total extracted in 1963 was exported. Japan produced only about 2 percent of the approximately 1,000 tons consumed in 1963, importing mainly from the Congo via Belgium. Less than one-tenth of the tin supply was from domestic ores, with the rest imported mainly as metal; however, Ishihara Sangyo Industrial Co., Ltd. was building a 750-ton-per-month tin smelter near Kuala Lumpur to give Japan more direct access to Malaysian tin. Nomura Mining Co., Ltd.'s Itomuka mine furnished less than one-fifth of Japan's 1963 requirements.

Japan produced significant quantities of gold in 1963, as byproducts of nonferrous base metal smelting. The country was the third ranking world producer of selenium, after the United States and Canada, and an important producer of zirconium. Many other minor metals were produced, including barium, beryllium, cerium, tantalum, and tellurium. Japan produced high-purity aluminum and zinc, but the best known high-purity metal products were silicon and germanium. The country's electronic-grade silicon output in 1963 ranked second in the world, following U.S. output.

NONMETALS

Cement.[5]—Japan probably was the third largest world producer of cement in 1963, surpassed only by the Soviet Union and the United States. The country was, as in several previous years, the world's foremost exporter of cement; the bulk of approximately 2 million tons exported in 1963 went to southeast Asia. While exports held somewhat steady, production and home consumption rose sharply between 1959 and 1960 and again between 1961 and 1962. Increasing amounts of cement were needed in Japan's construction and roadbuilding programs Although total cement plant capacity (42 million tons per year in September 1963) had already overtaken demand, additional facilities were still being installed. All kinds of cement were produced, headed by ordinary portland but including small tonnages of pozzolan, rapid hardening, heat resistant, blast furnace, and white cements. The country's raw material position for making cement was excellent, except that minor amounts of gypsum had to be imported in 1963.

During 1963, 21 Japanese firms produced cement, 1 more than in 1962. About 77 cement plants with about 190 kilns were in operation.

[5] Cement Information Service, Tokyo. Japan Cement Yearbook 1963 (in Japanese). V. 15, September 1963, p. 470.

Digitized by Google

Onoda Cement Co., Ltd. maintained its position as the leading cement producer, and its Tsukum plant in Oita was Japan's biggest. Nihon Cement Co., Ltd., was a close second to Onoda; in 1963, this company was building Japan's largest kiln, 205 meters long and 5.25 meters in diameter, at the Saitama plant. Sumitomo Cement Co., Ltd. (formerly Iwaki Cement Co., Ltd.) ranked third and Osaka Yogyo Cement Co., Ltd. fourth. Chichibu Cement Co., Ltd., with a large and modern plant of the same name, added more capacity at its smaller Kumagai plant in Saitama during 1963. Mitsubishi Cement Co., Ltd. expanded the Higashidani plant and installed a new large kiln at the Kurosaki plant in Kyushu. Daichi Cement Co., Ltd. similarily enlarged its Kawasaki plant. Higashidani and Kawasaki plants are equipped with dry kilns with high-heat efficiency suspension preheaters, forerunners of other such kilns to be built in Japan. Tokuyama Soda Co., Ltd. introduced computer controls on two kilns and reported good profit. Mitsui Cement Co., Ltd. was organized, but had not yet started production during 1963. There were signs that the very modern and strongly financed Japanese cement industry will continue to suffer from overproduction and excessive competition.

Fertilizer and Chemical Materials.—Japan's fertilizer and chemical industries, with a strong resource base in some raw materials and hardly any in others, retained their prominent world position during 1963. The fertilizer industry, producing 2.3 million tons of ammonium sulfate, 1.7 million tons of calcium superphosphate, 3.0 million tons of compound fertilizers, and 1.0 million tons of urea during the year, depended upon foreign markets, particularly the Far East, for about two-fifths of the sales. On the other hand, the basic chemical industry which produced approximately 5.0 million tons of sulfuric acid, 1.7 million tons of ammonium, 0.6 million tons of soda ash, and 1.0 million tons of caustic soda, essentially supplied the domestic market in making fertilizers and for other uses.

Nitrogen was mainly obtained by fixation. Almost all of the sulfur and pyrite consumed was domestic. Nearly four-fifths of the salt supply or close to 3 million tons had to be imported in 1963, since Japanese salt output from the Inland Seas declined. Japan was virtually totally dependent upon foreign potash and phosphate rock, importing over 1 million and 2 million tons, respectively, with potash mainly coming from the United States, Canada, and the Soviet Union and phosphate rock primarily from the United States.

The sulfur and pyrite industry of Japan, long of world importance with pyrite output exceeding that of any other country, did not undergo great change in 1963. The Yanahara pyrite mine of Dowa Mining still maintained its dominant position, and Matsuo Sulfur Co., Ltd. remained the principal elemental sulfur producer as well as an important supplier of mixed sulfur-pyrite ore to sulfuric acid plants. Of Japan's total sulfur output, about 5 percent (11,612 tons) came from oil refineries which were installing more recovery plants. The waste gases from oil refineries also provided nearly one-fifth of the sulfur for making sulfuric acid. Small amounts of sulfur were imported in 1963 at prices much lower than those paid for indigenous output. Japan's production of pyrite plus equivalent pyrites (such as pyrrhotite, cupriferous pyrite, and mixed sulfur-pyrite ore) totaled more than

Digitized by Google

3.5 million tons in 1963, with the nonferrous industry also contributing an important share. Although almost all of the pyrites were used as the sulfur material for making sulfuric acid, much of the pyrite cinder derived was subsequently sintered for use as a primary iron material.

Other Nonmetals.—In addition to cement and certain fertilizer and chemical materials, Japan produced an interesting variety of nonmetallics, some of world consequence but few in adequate quantities for consumption. One important exception is limestone, reserves of which may be as high as 50 billion tons. Japan was one of the world's largest producers of pyrophyllite, a talc substitute associated with clays. Feldspar output was also large by world standards. There were small but rapidly growing perlite and expanded shale industries. Another nonmetal produced in adequate quantities was barite. Asbestos imports were nearly eight times production, and came mainly from Canada. Fluorspar imports were about six times domestic output. Japan had a fair supply of clays, but sizable tonnages of good grade kaolin came from abroad. Only a small portion of the graphite and hardly any of the mica was locally produced. Talc output was about four times imports. Some high-grade glass sands were imported from South Vietnam.

MINERAL FUELS

Coal.—1963 was a bad year for the Japanese coal industry. Output of bituminous coal was down almost 2.4 million tons as compared with that of 1962 and several million tons below what the government and industry had hoped for. Pressure of imported fuel oil competition has mounted, and many marginal mines were shut down.

However, the most important single event contributing to the production decline was Japan's worst mine disaster in history at the Mikawa pit of Mitsui Mining Co., Ltd.'s Miike mine—normally a 5-million-ton-per-year operation—on November 9, 1963. The explosion left 348 dead and 487 injured, including the cream of the technical supervisors. As a result of investigations, shortage of personnel, and bad morale, Mikawa and two sister pits remained idle during the rest of 1963. Repercussions of the disaster were also serious in that large numbers of miners from this and other coal mines started to leave the industry to seek employment elsewhere.

The Japanese were doing their utmost to streamline the coal industry in the face of difficult mining conditions and handicaps in coal quality. Closure of smaller mines and sinking of new shafts improved the situation somewhat. Coal blending and making byproducts of coal were thoroughly investigated. The companies tried hard to diversify into endeavors such as transport, power, cement, and real estate, but with only a limited measure of success. The government was anxious to maintain a domestic annual output of about 55 million tons of coal.

Two major technical developments took place in the coal industry during 1963. There was a pronounced trend toward increased use of hydraulic mining, starting from the coal mines in Hokkaido. Meiji Mining Co., Ltd.'s Ponki mine, the only Japanese coal mine employing hydraulic methods exclusively, achieved improvements in productivity

Digitized by Google

and cost. Kaijima Coal Mining Co., Ltd., Nittetsu Mining Co., Ltd., Furukawa Mining Co., Ltd., and Aso Sangyo also used the method to some extent, and Mitsui Mining Co., Ltd. and Mitsubishi Mining Co., Ltd. were also looking into the concept. The Japanese Government made preliminary studies on slurry transport of coal from the Ishikari coal field to the port of Tomakomai in Hokkaido, and was hopeful that adoption of the method would have transportation charges, which presently constituted one-third of the price of the 13 million tons of Hokkaido coal shipped annually to the main island of Honshu.

Japan's basic shortage of coking coal continued, although some steam coal was imported in 1963 as a stopgap measure. Roughly 10 million tons of coking coal annually was imported during 1962–63, more than one-half from the United States and one-fourth from Australia. Blended with inferior quality domestic coals, Japan produced an annual average of nearly 15 million tons of coke in 1962–63, three-fourths for use by the steel industry. The importance of U.S. coal was much greater than implied by statistics in view of the quality, but its relatively high cost placed Australian coal within competitive range. The Japanese were negotiating for lower prices for U.S. coking coal, but instead were told of a slight price increase on account of wage boosts for U.S. coal miners. Such developments made Australian and other coals more attractive. Japan purchased more than one-half million tons of North Vietnam anthracite.

Petroleum and Natural Gas.—Japan's domestic petroleum production in 1963 was, even more than in past years, overshadowed by imports. Crude oil imports went up nearly 12 million tons, and fuel oil imports rose more than 1.5 million tons compared with that of 1962. Total imports, a fair gage of consumption, reached about 62.6 million tons or roughly 450 million barrels, compared with only 5 to 6 million barrels produced and a similar amount exported in 1963. The country's per capita oil consumption in 1963 was about the same order as that of the Soviet Union.

Japan was a very prominent world consumer of petroleum products and a refiner of crude oil, ranking fifth or higher. Refining capacity already installed ranks second only to the United States in the free world. An allied petrochemical industry, in full-fledged operation only since 1958, was expanded greatly in 1962–63.

The Japanese oil refining industry was in a state of confused rapid expansion. Big non-Japanese firms like Caltex, Esso, Socony Mobile, Tidewater, Shell, and British Petroleum owned large shares of Japanese oil companies, including many sales companies. This group, with their own crude oil supplies, controlled about two-thirds of Japan's 1963 petroleum refining capacity. The rest was in the hands of about seven Japanese firms, headed by Idemitsu Kosan Co., Ltd., Maruzen Oil Co., Ltd., Daikyo Oil Co., Ltd., and Nippon Mining. There has been constant jockeying for the right to build additional refinery capacity to meet the estimated total Japanese oil demand of 3 million barrels per day a decade from now. One-half of the 1963 applications for new refineries were turned down by the government. Since Japanese financial resources were and will continue to be short, foreign capital, particularly American, must play an important role.

Digitized by Google

Japan's energy supply has undergone a revolution from coal to petroleum in recent years, with the tempo quickening in 1963. The need for regulatory measures to moderate expansion, apportion oil markets, and set up standard prices was considered by the Japanese Government through Ministry of International Trade and Industry (MITI) and the industry to be desirable. Accordingly, the Petroleum Industry Law of 1962 was enacted in May, with implementation unfolding in 1963. This law, planned as a compromise between the business activities of the oil industry and national interest, was also introduced to counterbalance the liberalization of crude oil imports, which was accomplished in October 1962. Meanwhile, new problems developed, such as the question of accepting Khafji crude from Kuwait-Saudi Arabia Neutral Zone by domestic oil companies and the burning of unprocessed crude oil by the electric power companies. The petroleum law, with its approval system for refinery crude runs and expansion of facilities, made it easier for MITI to carry out its oil supply plans.[6]

Most crude oil imports came through the international oil companies operating in Japan or through direct purchases, with the Near East as a whole providing about four-fifths of the total. However, MITI's long-range program is for the Japanese to develop more new oilfields abroad, such as the northern Sumatra and Khafji operations, and a 57-percent profit scheme for the host country is acceptable The Khafji offshore field in the Neutral Zone, run by the Japanese firm, Arabian Oil Co., Ltd., has been of increasing importance to Japan. Imports from Khafji in 1963 amounted to 7.0 million kiloliters (about 44 million barrels), or nearly 12 percent of all Japanese crude imports and more than twice the 1962 level. Further great increases are imminent on the basis of 1964 data and new reserves found. Two new, very extensive offshore fields were reported in September 1963, namely Al Hout No. 1 with preliminary reserves of 1.34 billion metric tons and Khafji No. 44 with 0.8 billion tons.

Although small in comparison with imports, domestic crude output in 1963 rose about 4.2 percent over that of 1962. The Kubiki field of Teikoku Oil Co., Ltd., and Mitsuke field of Japan Petroleum Exploration Co., Ltd. (Japex) accounted for most of the output increase in recent years. Natural gas production more than tripled during 1959–63, reaching 1.695 billion cubic meters in 1963. Teikoku Oil's Sekihara field and Japex's Katakai field in Niigata were responsible for most of the increase in natural gas output. At the end of 1962, Japex completed a 205-mile natural gas line from Kubiki to the Toyosu plant of Tokyo Gas Co., Ltd. and a 42-mile oil line from Mitsuki to Niigata City. Japan's production of LPG gas has risen sharply during the last 5 years.

The Mineral Industry of North Korea

By K. P. Wang[1]

NORTH KOREA was a significant world mineral producer in 1963. Its estimated mineral output value of some US$400 million was a little lower than that of Yugoslavia in Europe and ranked the country approximately on a par with Indonesia after mainland China and Japan in the Far East. North Korea's mineral and metal output, in terms of per capita production value, ranked close to that of Japan.

North Korea has produced a variety of mineral and metal products, many in significant quantities by Far East standards. During 1963 the country ranked among the first five in world production of tungsten concentrate, graphite, and magnesite, thereby contributing about 7 to 13 percent of the total world production in each case. Production of mine and smelter lead as well as zinc, pyrite, and barite were 2 to 3 percent of the world total. The country also produced lesser shares of the world total of bismuth, cadmium, copper, gold, iron ore, pig iron, steel, cement, fluorspar, salt, talc, and coal.

North Korea's mineral industries are moderately well advanced technologically. Steel, nonferrous metals, and fertilizer industries are integrated to some extent although weak in fabrication. None of the other countries in the Far East except mainland China and Japan have corresponding facilities. North Korea was the third-ranking producer among Far East countries of coal and cement during 1963.

Minerals play a vital role in the economy; 10 to 15 percent of North Korea's 1963 gross national product (GNP) was derived from them. The bulk of production has been traditionally consumed locally, meeting an increased industrial demand. However, exports remained important, particularly lead, tungsten, zinc, barite, fluorspar, graphite, magnesia clinker, and talc.

Important advances were made in many mineral industries during 1963. In the iron and steel sector, developments centered around the construction of rolling mills and mine concentrators. However, progress in developing Kimchaek into a large integrated steel plant was slow. In the nonferrous metals industry, construction of a new zinc plant was started, a copper rolling mill was completed, and a Waelz kiln and heavy media facilities were being built. Cement production was raised through more efficient operations, and refractory facilities, particularly magnesia clinker, were greatly expanded. A number of new shafts were completed in the coal industry during 1963, and mine transportation as well as the handling of materials were improved.

However, coal output, although surpassing 1962 figures, fell short of the 1963 target.

GOVERNMENT POLICIES AND PROGRAMS[2 3]

North Korea, the industrial half of the Korean Peninsula where about 11 million people live, made significant progress in economic and industrial development in recent years. The GNP growth in both 1963 and 1962 over that of the previous years was claimed to be about 10 percent. The industrial output growth in 1963 was reportedly 8 percent over that of 1962 and that in 1962 was 20 percent over that of 1961. Industry contributed about three-fifths of the GNP in 1963 and was more than twice as important as agriculture. Minerals and related industries accounted for about one-fourth of the industrial output in 1963.

Ever since the establishment of the present government after World War II, stress has been placed on the development of basic industries, many of which are mineral industries. Enlargement of existing facilities and creation of many new ones has resulted in a steady rise in mineral and metal production, increased diversification of products, and growing capability in smelting and processing. The country's natural mineral resource base is exceptionally strong, except for oil—a deficiency partly compensated by extensive and well-developed hydroelectric power and exploitation of sizable reserves of coal. North Korean Government policy in the mineral field has been to attempt to meet the growing industrial requirements of the country from domestic resources, importing as little as feasible, and exporting as much as possible and in forms that are most advantageously marketable.

PRODUCTION

Mineral output of North Korea has shown an overall steady increase in recent years, the estimated value for 1963 of some $400 million being roughly 10 percent greater than in 1962. The country has developed a metallurgical component of the mineral industry that contributed roughly one-fourth of the mineral production gross value.

Coal accounted for about one-third of the 1963 mineral output value, iron and steel one-fourth, cement one-fifth, nonferrous metals one-eighth, and miscellaneous nonmetals the remainder. Thus, not only was the country an important mineral producer relative to its size, but it also had relatively well balanced and diversified mineral and metal facilities.

North Korea's level of mineral development and industrialization is illustrated by the 1963 production of approximately 14 million metric tons of coal, 1 million tons of steel, 180,000 tons of nonferrous metals (two-thirds in the metallic form), 2.5 million tons of cement, 2 million tons of other nonmetals, and 850,000 tons of various kinds of fertilizers.

Digitized by Google

During 1959–63, iron and steel output more than doubled, coal output rose by nearly three-fifths, and cement production increased in excess of one-quarter. Nonferrous metals showed a small increase in mine output and a substantial increase in metal output on account of new and expanded smelting facilities. Sizable capacities for producing various nonmetallics have been developed in the last 5 years.

TABLE 1.—Production of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity [2]	1959	1960	1961	1962	1963
Metals:					
Cadmium, electrolytic	20	50	80	90	100
Copper:					
Mine	5,334	6,000	6,000	8,000	8,000
Electrolytic	4,970	8,200	8,000	10,000	10,000
Gold, troy ounces	160,000	160,000	160,000	160,000	160,000
Iron and steel:					
Iron ore [3], thousand tons	2,703	3,108	3,550	3,340	3,860
Pig iron [4], do.	694	853	930	1,213	1,159
Steel ingot, do.	451	641	776	1,050	1,022
Rolled steel, do.	331	474	536	633	762
Ferroalloys, do.	15	17	20	25	25
Lead:					
Mine	40,000	50,000	50,000	50,000	50,000
Smelter, primary	20,000	30,000	40,000	40,000	40,000
Nickel, electrolytic	200	300	400	400	400
Silver, troy ounces	320,000	500,000	640,000	640,000	640,000
Tungsten concentrate	4,000	5,000	5,000	4,000	4,000
Zinc:					
Mine	85,000	85,000	90,000	90,000	100,000
Electrolytic	25,000	50,000	60,000	60,000	65,000
Nonmetals:					
Apatite	50,000	100,000	150,000	200,000	200,000
Barite	15,000	40,000	55,000	60,000	70,000
Cement, thousand tons	1,926	2,285	2,262	2,376	2,530
Fluorspar	30,000	30,000	30,000	30,000	30,000
Graphite	52,000	62,000	65,000	65,000	70,000
Magnesite:					
Ore as mined, thousand tons	50	50	200	500	800
Clinker, do.	----------	20	100	200	385
Pyrite, do.	200	250	300	350	400
Salt, do.	400	324	392	421	450
Talc and soapstone, do.	2,000	4,000	15,000	20,000	20,000
Mineral fuels:					
Coal, do.	8,359	10,620	11,790	13,200	14,040
Anthracite, do.	5,535	6,778	7,500	9,000	9,700
Bituminous [5], do.	3,117	3,524	4,000	4,000	4,000
Other, do.	207	318	290	200	340
Coke, do.	703	817	900	1,100	1,200

[1] All figures are estimated, except for iron and steel items (ferroalloy data available for 1959–60 only), copper (data available for 1959 and earlier), cement, graphite (data available for 1959–60 only), magnesite (data available for 1963 only), salt (data available for 1960–62 only), coal (breakdown data available for 1959–60 only), and coke (data available for 1959–60 only). The firm figures are official North Korean data.

[2] Many other mineral commodities are produced, but reasonable output estimates cannot be made. These include antimony, beryl, bismuth, chrome, cobalt, manganese ore, mineral sands (ilmenite, zircon, columbite, rutile, monazite), minor and rare metals (selenium, tellurium, germanium, indium, silicon), molybdenite; and alum, arsenopyrite, asbestos, boracite, clays, kaolin, lepidolite, limonite, mica (phlogopite), and silica (including glass sands).

[3] 1959–61 data apparently represent crude ore, most of which was 30 to 40 percent Fe grade. 1962–63 data undoubtedly included some concentrates.

[4] Includes Krupp-Renn granulated iron or luppe.

[5] Low calorific value, much of which might be classified as low-rank coals.

With the aid of the Soviet Union and other Communist countries, North Korea concluded a 5-year plan in 1960, raising overall industrial output to a level several times the peak of what it was during the Japanese occupation. The objective of the present 7-year plan covering 1961–67 is roughly to triple the 1960 production. Experi-

Digitized by Google

ence indicates that performance may be slightly below expectations. Data on the 1963 output, the 1964 plan, and the 1967 targets for selected major mineral and related commodities show that North Korea still has a long way to go in meeting its ambitious objectives.

TABLE 2.—Production and production goals for mineral products and energy

(Million metric tons unless otherwise specified)

Commodity	1963 output	1964 quantity plan	1967 target
Electric energy.....kilowatt hours	11.77	(1)	17.0
Coal	14.04	16.00	23.0 to 25.0
Iron ore	3.860	4.0	7.0 to 7.5
Pig and granulated iron	1.159	1.270	2.2 to 2.5
Steel ingot	1.022	1.167	2.2 to 2.5
Rolled steel	.762	.870	1.6 to 1.8
Chemical fertilizers	.853	.950	1.5 to 1.7
Cement	2.530	2.780	4.0 to 4.5

[1] Data not available.

TRADE

North Korea is a significant mineral exporting country, particularly in nonferrous metals and in nonmetals. Mineral and metal exports in 1963 probably were on the order of US$50 million or perhaps one-eighth of production. This points out that mineral consumption in the country also has attained fairly high levels.

Specific official trade information by the North Korean regime is not available, but the predominant share of the trade has been with the Communist nations, particularly the Soviet Union and to a lesser extent mainland China. Japan and, very recently, Great Britain were North Korea's main free world trade outlets. These generalizations on overall trade are equally valid for mineral trade. In the absence of official North Korean statistics, mineral imports by the Soviet Union and Japan from North Korea and petroleum exports by the Soviet Union to North Korea have been substituted. The magnitude of North Korean mineral exports to other Communist countries was not known but was believed to be smaller than the combined total for the U.S.S.R.

The Soviet Union has imported substantial quantities of primary lead and zinc materials from North Korea, but the proportion of concentrates has been declining in line with greater Korean smelting capacity. It has imported quantities of Korean pig iron, rolled steel, and cement, presumably for use in the Soviet Far East. North Korean barite (for oil drilling), magnesia clinker, and talc have been finding growing markets in the U.S.S.R. No doubt the Soviet Union has imported sizable amounts of North Korean tungsten concentrate and lesser metals like cadmium and bismuth, but this has not been reported. Soviet petroleum has been indispensable to North Korea. Other Soviet exports to North Korea have included ferroalloys, steel pipes, rolled nonferrous metals, and asbestos.

Mineral trade between North Korea and Japan was already moderate and diversified. In addition to the items traded in 1962, negotiations between the two parties late in 1963 indicated that Japan might

Digitized by Google

obtain more Korean iron concentrate, from Musan, as well as 100,000 tons of pig iron, and some nickel-cobalt materials in exchange for mineral and metal products like tinplate, steel wire and pipe, ferroalloys, and aluminum ingot. Great Britain and North Korea signed an important two-way trade contract in November 1963 whereby British sheet steel products (tinplate as well as hot and cold rolled sheets) will be traded for Korean lead and zinc.

COMMODITY REVIEW

METALS

Iron and Steel.—North Korea's roughly 1-million ton steel industry recorded slight declines in pig iron and steel ingot output in 1963 as compared with 1962 figures. However, rolled steel production reportedly exceeded that of the previous year by about one-fifth. Some 50 types of new rolled steel products were said to have been produced, with the most notable advances in thin steel plate and wire rope. Finished steel products, particularly coated and uncoated sheets, represented a weak aspect of North Korea's iron and steel economy and, in late 1963, contracts were signed with Japanese and British traders to obtain these items.

At the Hwanghae (Whanghai) steelworks, and the country's largest and only integrated plant located south of P'yongyang along the southwest coast, construction of a 400,000-metric-ton blooming mill to complement other existing facilities made important headway in 1963, following the completion of two 40-metric-ton oxygen converters. Progress in making Kimchaek on the east coast into a large integrated steel plant was slow in 1963, although first-stage construction up to converter steel facilities (no rolling mill yet) on a scale slightly smaller than Hwanghae had already been completed.

Kangson, located north of the Hwanghae steelworks, produced both electric and Bessemer converter steel but no pig iron and specialized in shaped steel products; a 300,000-ton rolling mill started operations in late 1962 and a 50,000-metric-ton seamless pipe mill was nearly completed by the end of 1963. Songjin on the east coast produced electric pig iron and special steels and had a 200,000-ton-metric rolling mill including a recently completed 80,000-metric-ton heavy plate mill. Chongjin, the country's fifth steel plant in the northeast corner of North Korea primarily produced "granulated iron" (capacity about 130,000 metric tons per year) by the Krupp-Renn rotary furnace process.

North Korea has adequate iron ore to support a moderate steel industry, but the ore is mostly of inferior quality requiring upgrading. The foremost iron mine, Musan, in the east near the Manchurian border, already had sufficient milling facilities but an improved concentration method was being considered; one new project completed in 1963 was a large ore conveyance facility at the open pit. At the Mandok magnetite-pyrite mine in Hamgyong-Namdo, construction of a 280,000-metric-ton concentrator made headway in 1963. Also, during the year, a mill capable of producing 400,000 tons of concentrates from nearly 1 million tons of ore went into operation at the Unyul (Ullyul) open-pit limonite mine near P'yongyang.

Because of the shortage of coking coal, mostly supplied by mainland China, the low-grade nature of the magnetite and limonite, and moderate pit iron output levels, the high-shaft blast furnace operation—the principal method now employed—is not felt to be the most advantageous for the future. Electric pig iron smelting is also considered expensive in many cases. The long-range thinking of the

Digitized by Google

North Koreans, as of 1963,[4] was to build more granulated iron continous steelmaking (combination Krupp-Renn and steel refining) facilities together with conventional facilities. The use of ferrocoke (coking coal mixed with fine iron ore) in blast furnace smelting is an interesting North Korean innovation. At the end of the present 7-year plan, the hope is to produce three-fifths of the steel by the oxygen converter method.

Zinc, Lead, and Copper.—North Korea's mine output of zinc, lead, and copper in 1963 were significant. The regime envisages doubling the value of nonferrous production in a few years. The plan to increase values includes raising mine output somewhat, particularly copper, creating more smelting and processing facilities, and producing a greater variety of nonferrous metals and alloys. As in previous years, there were sizable surpluses of lead-zinc concentrate and metal in 1963.

At Munpyong the big lead-zinc smelter in the central coastal part of the country, a large sulfuric acid plant was reportedly installed to complement the 40,000-metric-ton electrolytic zinc plant completed in 1960; recent information indicates that the building of a Waelz kiln unit was well underway in 1963. The Poles reportedly were helping North Korea to build another zinc plant of 15,000 tons, with corresponding sulfuric acid facilities, that might become operative by 1965.

The most important recent development at the Namp'o copper-zinc smelter on the west coast was the completion of a 12,000-metric-ton copper rolling mill with wire and cable units. As of 1963 the smelter had diversified facilities—fluosolid reactors, 5,000-ton-plus copper refinery, 20,000-ton electrolytic zinc refinery, gold and other byproduct units, as well as sulfuric acid and superphosphate units. North Korea's third major nonferrous smelter was Hungnam to the northwest of Munpyong. In addition to copper and gold, Hungnam treated antimony, manganese, tungsten, molybdenum, and nickel.

Developments at specific base metal mines during 1963 are not known, but most operations have been fairly well stabilized for some time. The principal lead-zinc mines are in Kwangchon and Hochon in Hamgyong-namdo, Yongnim and Nangnim in Chagangdo, Songchon in P'yongan-namdo, and Ongjin and Changyon in Hwanghaenamdo. In 1963, heavy-media separation was reportedly introduced in lead-zinc operations. The two main copper mines of North Korea were Kapsan in Yanggando and Hwap'yong in Changangdo, with the former much the more important.

OTHER METALS[5]

Production of precious metals in North Korea was obtained primarily as byproduct output from copper and lead-zinc operations. The country had mines producing mainly gold; however, the relative importance of these has declined as base metal recovery has increased.

Digitized by Google

At the Holtong gold-copper-scheelite mine in Hwanghae-pukto (North Hwanghae Province) construction of a 410-meter vertical shaft was well underway in 1963.

During 1963, the Inp'yong Mine continued to be the sole producer of antimony ore and sent its output to Hungnam for smelting. Important quantities of electrolytic cadmium were recovered from zinc refining, and bismuth was recovered from lead smelting. Minor metals like selenium, germanium, indium, and silicon were also produced by the nonferrous smelters in 1963. North Korea has mined mineral sand (containing ilmenite, zircon, rutile, and monazite) for many years, although the level of production is not known.

North Korea has long been a producer of tungsten concentrate, mostly wolframite but also scheelite. The two leading mines are apparently Sinp'yong in Hwanghae-pukto and Taehung in Hamgyong'-namdo (South Hamgyong Province). The last reported output figure is 2,418 metric tons of concentrate in 1957, about three-fifths of the probable 1963 level. Some of the tungsten is consumed locally in making high-speed alloys and tool steel. Nickel-cobalt ores containing several hundred tons of nickel yearly are extracted at the Toksan Mine and elsewhere and made into electrolytic nickel at the Hungnam smelter. Chrome and manganese ore were also produced in 1963; manganese ore production apparently was not adequate for domestic demand.

The country has the raw materials and power to make magnesium. There is local demand for aluminum, and the North Koreans are considering resumption of production by 1967, with a 20,000-ton reduction plant based upon nephelite.

NONMETALS [6]

Barite.—By exploiting deposits at Changdo in Kangwon-do, Sugyo in Hwanghae-pukdo, Sokkge in P'yongan-pukto, and Tongchang in Hwanghae-namdo, North Korea has suddenly emerged as a significant barite producer.

Cement and Other Construction Materials.—North Korea has steadily expanded its cement industry; 1963 production came from about six 150,000- to 600,000-ton plants scattered around the country. Raw materials are generally adequate, except for gypsum which was imported in part from mainland China. The lime, brick, ceramics, and refractory materials industries were also sizable.

Chemical and Fertilizer Materials.—As of 1963, a fairly well balanced basic chemical and fertilizer industry with a strong raw material base as well as sulfuric acid and soda components already had been established. Pyrite, the source of sulfur, was extracted according to need, and sea water salt operations had a reasonably good year. Large quantities of apatite, mainly from the Sinp'ung mine in Hamgyong-namdo, were mined and utilized to make superphosphate. Nitrogen-fixation with hydroelectric and thermoelectric power provided the nitrogen base. North Korea's two principal chemical and fertilizer

Digitized by Google

centers in 1963 were Hungnam and Namp'o, both with superphosphate plants.

Graphite.—North Korea is a traditional graphite producer but by far the bulk of its 1963 production was amorphous grade. The crystalline grade component apparently has declined in relative importance in recent years.

Magnesite.—The North Koreans officially reported 385,000 metric tons of magnesia clinker output for 1963, making the country a prominent world producer and exporter of this material. Much of the magnesia clinker was made at plants in Chongjin and Songjin, both in Hamgyong-pukto. Extensive and high-grade magnesite reserves are known to occur in the Machon Mountain Range.

MINERAL FUELS

North Korea's output of fuels and power showed only a slight improvement in 1963 over that of 1962. Indigenous coal (primarily anthracite) and hydropower remained as the principal sources of energy consumed. Petroleum has been traditionally imported, mainly from the Soviet Union. Its use has been carefully controlled and solid fuels and electricity have been substituted for oil whenever possible. Wood and vegetable materials have played a minor role in industrial-scale heat and power generation. The 11.8 million megawatt-hours of electricity reportedly produced from all thermal and hydropower sources in 1963 ranked Korea high among world nations on a per capita basis. Many potential hydropower sites on the Yalu and other rivers remain to be developed.

Coal.—Coal production gains in 1963 fell slightly short of target. There was need to block out more reserves in order to increase the rates of extraction. Much basic work was done in mine transportation, such as electric railroads at the Anju brown coal mine, belt conveyors at the Bongchon and Choyang (open-pit) anthracite mines, and heavier tracks at the Yongdong mine. During 1963, vertical shafts were completed at the Aoji, Kokonwon, and Hamyon anthracite collieries. For the anthracite mines, mainly located in P'yongan-namdo in the west, special efforts were made in underground drainage which constitutes a problem in the rainy season. Modifications were made in mining methods for many mines, and hydraulic mining was reportedly introduced. Conservation of timber was stressed. Output at the Sinchang anthracite mine in the central Taedong River Basin—largest coal mine in North Korea—topped 2 million tons in 1963.

The bituminous coal situation apparently did not improve during 1963, much of the output included in this category being actually lower rank coals. Good-grade bituminous coal had to be imported from Manchuria in China, primarily Shuang-ya-shan, for coking purposes. To cut down the import requirements, anthracite has been used as much as possible in blast furnace smelting, electric smelting has been stressed, and greater application of iron and steelmaking methods requiring little or no coking coal, such as the Krupp-Renn process, has been considered. Anthracite was not only the principal fuel for

Digitized by Google

thermal power in 1963, but also was used in chemicals and ammonia fertilizers. Low-rank coals, mostly extracted in Hamgyong-pukto, were important as fuel for railroads although thought was given to converting such coals into electricity to supply electrified railroads in the future.

The Mineral Industry of South Korea

By J. M. West [1] and K. P. Wang [2]

SOUTH KOREA's economy is chiefly agricultural, in contrast to that of North Korea, a much more industrialized country. With a population of 27 million, South Korea produced approximately US$150 million worth of mineral products in 1963. In comparison, North Korea, with two-fifths of that population, produced more than 2.5 times the mineral value of South Korea. Although South Korea is mineral-poor, compared with its northern neighbor, some leading mineral products such as anthracite, tungsten, and graphite, are common to both countries. Most of South Korea's larger mineral and industrial enterprises are controlled by the government.

Anthracite has been South Korea's most important mineral product in terms of value in recent years, replacing tungsten, for which the country had been most noted. The output value of anthracite in 1963 was 1.5 times that of all the other mineral and metal products combined, and twice the combined value of the next two ranking categories, which were cement and iron and steel. Lesser mineral industries included iron ore, tungsten-bismuth, gold, graphite, and salt. The nonferrous base metal industry is small, but the country has produced fair amounts of nonmetallics, such as fluorspar, talc, and pyrophyllite.

South Korea provided about one-half of the world's graphite in 1963, but the material was poor in grade. It probably was also the third-ranking world producer of tungsten, accounting for over 10 percent of the total and more than 25 percent of the free world supply. In addition, South Korea produced approximately 9 percent of the world's anthracite, 5 percent of the bismuth, and 2 percent of the fluorite (fluorspar).

Minerals and metals were significant to the country's economy; combined output value in 1963 was approximately 7 to 8 percent of the gross national product. Anthracite mining probably was the most important single industrial activity in South Korea. The mineral industry as a whole has grown consistently in recent years; progress has been particularly strong in 1962–63.

Probably the most important mineral development in 1963 was the near completion of a petroleum refinery at Ulsan, a large industrial complex being constructed on the southeast coast. Plans for building an integrated steel plant at Ulsan were scaled down and remained under study. A 20,000-ton steel-rolling mill was opened at

[1] Physical scientist, Division of International Activities.
[2] Chief specialist, East Europe-Far East, Division of International Activities.

Digitized by Google

Toksu near Seoul. Agreements were reached to build mixed nitrogen-phosphate-potash fertilizer plants at Ulsan and Changhang. Coal production increased at a rate exceeding government plans. Three cement plants were under construction, two in Chungchong-pukto (North Chungchong Province) and one in Kangwon Province. A fluorspar-processing mill went into operation at Kumsan, Cholla-Pukto (North Cholla Province). Owing to unfavorable markets, operations at the Sangdong mine were curtailed and tungsten production declined. The search continued for iron deposits to supply the proposed Ulsan integrated steel plant and the growing export trade with Japan. At Changhang, the country's only base metal smelter, lead smelting and gold-silver cyanidation plants were under construction.

GOVERNMENT POLICIES AND PROGRAMS

The government's 1962–66 5-year plan emphasizes improvements in electric power, coal mining, transportation, and communications; and construction of additional cement and fertilizer facilities, an oil refinery, and a steel mill.[3] Greater production of iron ore and tungsten is also planned. A fundamental objective of the plan is to cut down on unfavorable trade balances.

Government-controlled industries, such as the Daihan Coal Corp., Daihan Iron Mining Corp., Daihan Mining & Smelting Corp., and Korea Tungsten Mining Corp., were authorized under the Mining Development Assistance Act (law 1089) of June 1962 to extend financial and technical aid to private companies for development projects. An enforcement decree issued in August 1962, outlined specific areas of responsibility in the mineral field. The Mining Encouragement Decree (as amended, Cabinet Decree 1234) enacted in March 1963, established procedures for the Ministry of Commerce and Industry to subsidize exploration, mills, and mine roads and to lend equipment to private mine owners and developers. The Mine Safety Law (law 1292), also enacted in March 1963, provided severe penalties to mine operators for violation of Ministry of Commerce and Industry orders to suspend operations because of unsafe conditions, equipment, or mining methods.

Increased emphasis was placed on fuels and power. Most of the power industry is government owned. Thermal plants under construction were expected to consume an additional 1 million tons of coal annually. A U.S.-financed 132,000-kilowatt thermal plant was being built near Pusan in 1963, and construction was to begin on a German-equipped 100,000-kilowatt thermal plant at Yongwol. A

[3] Republic of Korea, Economic Planning Board (Seoul). Summary of the First Five-Year Economic Plan, 1962–66. January 1962, 88 pp.

Digitized by Google

30,000-kilowatt generator was installed at the Samchok thermal plant. The Agency for International Development (AID) authorized a US$12.8 million loan for a 66,000-kilowatt thermal plant at Kunsan near the Changhang smelter. Work continued on the 57,000-kilowatt Chunchon hydroproject on the North Han River and the 35,000-kilowatt Uiam project on the Han River upstream from Chongpyang. South Korea's total generating capacity at the start of 1963 was rated at 434,000 kilowatts, scheduled to be increased to 678,000 kilowatts by 1965.

Assisting in South Korea's resource development program, the Mineral Industries Engineers, Inc., of Golden, Colo., completed geophysical and geological studies under an AID contract in 1963 and signed a new contract extending to July 1965.

The metric system, used on a trial basis during the last quarter of 1963, was adopted officially by South Korea for all statistics and measurements, effective January 1, 1964.

PRODUCTION [4]

Mineral output of South Korea roughly doubled in value between 1959 and 1963, and the estimated figure of US$150 million in 1963 was about 15 percent greater than in 1962. The metallurgical component of the mineral industry was small, because of the poor resource potential in metallic ores and the relatively low level of industry activity.

Coal accounted for about 60 percent of the 1963 mineral output value, cement and steel each 10 to 15 percent, and nonferrous metals and nonmetallics each 5 to 8 percent. Other mineral-producing operations were small, compared with coal mining and steel and cement production. A decade ago tungsten was also important, because prices were more than five times the present level.

Anthracite and cement more than doubled and steel quadrupled from a nominal base in the past 5-year period. Gold production increased by about 50 percent, and a small nonferrous industry was developed during these 5 years. Tungsten output in 1963, while much higher than in 1959, was well below that of 1962, reflecting the drastic decline in prices. In the nonmetallic area, graphite operations were greatly expanded. The barite, fluorspar, pyrophyllite, and talc industries either were new or bore no resemblance to their small-scale beginnings of 5 years ago. Salt production has fluctuated owing to varying weather conditions.

TRADE

Minerals and metals were important in South Korea's trade, accounting in value for about one-fifth of both exports and imports in 1963. However, mineral exports were less than US$20 million, whereas mineral imports exceeded US$100 million. Aside from South Korea's three main mineral products (anthracite, cement, and steel), many others, except precious metals, are primarily exported. The two principal categories of mineral imports are petroleum and steel products, which together constituted two-thirds of the value of all mineral imports in 1963. South Korea has been entirely dependent on foreign crude and refined oil.

Japan and the United States have been South Korea's principal trading partners. More than two-thirds of the 1963 mineral exports went to Japan; the only important item going primarily to other destinations was tungsten. Japan also furnished South Korea with about one-fourth of the mineral imports, primarily steel products and secondarily cement and fertilizers. The United States took half of the country's tungsten, and furnished the bulk of the oil, nonferrous metals, sulfur, and phosphates. The U.S. share of South Korean mineral imports was 40 to 50 percent.

TABLE 2.—Exports of selected metals and minerals

(Metric tons)

Commodity	1961	1962	1963	Principal destinations, 1962
Metals:				
Copper	733	40	(1)	Mainly to Japan.
Iron and steel [2]	8,079	2,594	46,663	Mainly to South Viet-Nam.
Iron ore	443,818	363,988	549,647	Japan 342,903.
Lead concentrate	1,622	1,443	4,982	All to Japan.
Manganese ore	500			
Nickel ore	750	916	546	All to Japan.
Tungsten ore and concentrate	5,927	4,713	5,107	United States 2,301; Western Europe 2,006; Japan 173.
Zinc concentrate	560	725	3,144	All to Japan.
Nonmetals:				
Barite	951	299	1,688	Japan 59.
Fluorspar	33,383	23,611	31,896	Japan 22,354.
Graphite [3]	57,450	47,379	47,416	Japan 44,975.
Kaolin	12,257	7,741	13,845	Japan 7,655.
Talc	14,508	18,369	17,570	All to Japan.
Mineral fuels: Anthracite	241,286	301,487	262,954	Do.

[1] Data not available.
[2] Consists of all pig iron in 1961 and all steel plates and sheets in 1962 and 1963.
[3] Includes crystalline graphite estimated at 1,200 tons in each year.

Steel trade increased sharply in 1963, with imports of products reaching about 300,000 tons, more than double the 1962 rate; exports rose from a few thousand tons to nearly 50,000 tons, primarily to South Viet-Nam. Scrap iron import of 30,000 tons in the first half of 1963 was a fourth higher than in all of 1962. Petroleum imports in 1963 increased by about one-third over the 1962 figures, cement imports rose about 50 percent, and bituminous coal imports declined about 30 percent.

TABLE 3.—Imports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	Principal sources, 1962
Metals:				
Aluminum	3,471	11,804	7,653	United States, Taiwan.
Brass, bronze, other copper alloys	85	524	517	Japan.
Iron and steel:				
Scrap iron	150	22,300	(1)	Far East.
Ferroalloys	2,285	5,471	4,855	Western Europe.
Steel ingots	19,038	1,489	44,421	West Germany.
Semimanufactures [2]	32,008	129,165	238,557	Japan, Western Europe.
Mercury	17	25	(1)	United States.
Tin	164	318	218	Malaya.
Titanium oxide	1,015	1,312	983	United States, Japan.
Zinc	4,712	5,017	10,467	United States.
Nonmetals:				
Cement	75,647	180,385	274,294	Japan.
Gypsum and plasters	21,197	22,093	29,972	Mexico, Japan.
Magnesite	507	1,722	2,077	Austria, Japan.
Sulfur	7,647	217	1,476	All from United States.
Superphosphate	47,277	56,369	27	United States, Japan.
Mineral fuels:				
Bituminous coal	281,685	180,018	130,208	Taiwan, Australia.
Petroleum refinery products: [3]				
Gasoline thousand 42-gallon barrels	949	701	630	United States.
Kerosine do	310	390	402	Do.
Distillate fuel oil do	1,182	1,932	3,579	Do.
Residual fuel oil do	2,553	3,923	4,514	Do.
Lubricants do	64	91	234	Do.
Other do	196	279	452	Do.
Total do	5,254	7,316	9,811	Do.

[1] Data not available.
[2] Includes steel plates and sheets totaling 17,661 tons in 1961, 63,480 tons in 1962, and 149,244 tons in 1963.
[3] Excludes petroleum products used for military purposes.

Source: Research Department, the Bank of Korea, Seoul.

Exports of tungsten concentrates, still mainly to the United States and Western Europe, were a little higher, despite slightly lower production. Iron ore exports in 1963 rose more than 50 percent over the 1962 figures, fluorspar exports increased 35 percent, and anthracite exports declined by about 15 percent. Most of these developments reflect greater industrial activity and higher mineral production and consumption in South Korea.

COMMODITY REVIEW

METALS

Copper.—Changhang has a small copper smelter and electrolytic refinery plus a 100-ton flotation mill, treating scrap and copper ores from a few small mines. Two additional facilities under construction in 1963 were due for completion in 1964; a 30-ton-per-day lead smelter and a 25-ton-per-day cyanidation plant for treating gold-silver ores.

Gold.—South Korea's gold comes mainly from straight lode-type gold mines, although there are small placer and nonferrous smelting operations. Estimated 1963 output was more than 15 percent less than in 1962, a year when substantial gold was recovered at the Kwangyang mine in development work. Normally, over one-half of the country's gold output is from the Kubong and Muguk mines.

Digitized by Google

Iron and Steel.[5]—Demand for steel increased sharply in 1963 owing to a construction boom. As a result, output of steel ingots and imports of steel products [6] more than doubled the 1962 rate. Apparent consumption of steel products in 1963 exceeded 400,000 tons, compared with ingot production of only some 160,000 tons. AID-financed steel exports (mostly sheets and plates) were expected to be short lived because of reduced export subsidies and other restrictions. The existing scrap-based steel industry and small plants processing intermediate steel products have not been able to meet the growing needs of South Korea, and the iron ore industry has been purely an export industry.

The heart of South Korea's 1963 steel enterprise was the Inchon plant near Seoul; the plant belongs to the government-owned Daihan Heavy Industry Corp. Its 50-ton open-hearth furnace and 100,000-ton-per-year medium-section rolling facility turned out nearly one-third of the country's steel output, including most of the 10,000 tons of sheets. The rest of the output, which consisted mainly of rods and bars, was provided by about 30 other small and mostly privately owned steel plants, with overall about 3 open-hearth furnaces (3- to 10-ton size), 12 electric furnaces (1- to 5-ton size), 12 converters (1- to 5-ton size), and 50 rolling mills. These latter plants had to use supplementary imported steel ingots and blooms amounting to over 40,000 tons in 1963. Some operations worked on imported uncoated sheets and produced roughly 32,000 tons of galvanized sheets for South Korea.

In September 1963, the Zion Iron & Steel Industrial Co., Ltd., started to operate its 20,000-ton rolled-steel plant at Toksu, east of Seoul on the Han River. Two 60-ton melting furnaces had been installed and three 120-ton unspecified furnaces were under construction. The raw material for this plant may have to be imported scrap or steel ingot.

Plans originally submitted in November 1962 by Korea Steel Co. and Blaw-Knox Associates for an integrated iron and steel plant in the Ulsan industrial complex were scaled down to 304,000 tons of pig iron, 202,000 tons of steel ingot, and 178,000 tons of rolled products. The revised project under study will cost about US$80 million and was rated a key item in the government's 5-year plan. Emphasis was expected to be placed on sheet products, which South Korea produces in only very small quantities.

As of 1963, the iron ore reserve needed for an integrated steel plant plus exports was far from assured. The most optimistic reserve estimate credits South Korea with only about 20 million tons of iron ore, perhaps one-third of which is proved. The 500,000 tons produced for the Japanese market in 1963 would not be adequate for the proposed Ulsan plant even if not exported. Korea's leading mine, Yangyang in Kangwon Province, has only 5 to 8 years of reserves for an annual output of 300,000 tons of iron ore. AID-sponsored aerial and ground

[5] Far Eastern Economic Review (Hong Kong). Steel for Asia. V. 42, No. 13, Dec. 26, 1963, pp. 677–678.

[6] Iron and steel imports (excluding scrap) during 1963 consisted of 4,855 tons of ferroalloys, 44,421 tons of steel ingots and blooms, 15,498 tons of steel wire and rods, 14,521 tons of steel bars and shapes, 149,424 tons of steel sheets and plates (mostly uncoated), 25,463 tons of hoops and strips, 18,309 tons of rails and accessories, and 15,522 tons of steel tubes and pipes.

Digitized by Google

geological surveys led to the discovery of 2 million tons of 56 percent iron ore at Mulgum in South Kyongsang Province, where ore shipping began in mid-1962.

Lead-Zinc.—Output of lead and zinc concentrates rose significantly in 1963. There were only a few lead-zinc mines, probably the largest being the Sihŭng. Battery scrap supplied most of the country's lead requirements, since lead concentrates are exported.

Tungsten, Bismuth, and Molybdenum.—Much of South Korea's 1963 tungsten concentrate output consisted of synthetic scheelite, but some natural scheelite and wolframite concentrates were also produced. Over 90 percent came from the Sangdong mine, world famous for its size and richness. Synthetic scheelite was produced from the lower grade ores at Sangdong in a 400- to 450-ton-per-month plant opened in 1960; it is considered to be the world's largest such operation. Dalsung supplied some wolframite. Both mines are operated by the government's Korea Tungsten Mining Corp. (KTMC).

The market for tungsten, historically an important foreign exchange earner for South Korea, was depressed in 1961–63, mainly because of dumping of mainland Chinese tungsten in Western Europe. Prices fell below US$9 per short-ton unit there, and were only several dollars higher at the end of 1963. South Korea was only enabled to sustain operations by the synthetic scheelite plant, which could treat previously unworkable ores. Toward the end of 1963, mine production at Sangdong was curtailed somewhat in order to use up several thousand tons of impure concentrate on hand.

A tungsten metal plant being built by KTMC at Yŏngdŭngp'o, a Seoul suburb, was scheduled for completion by the end of 1964. Wah Chang Corp. of New York provided technical assistance.

Bismuth has been a valuable byproduct of tungsten in South Korea, output generally representing about 5 percent of the world total. Virtually all is from the Sangdong mine, where bismuth content of ores amounts to about one-tenth the weight of scheelite. Metallic bismuth of 99.7-percent grade or better is produced at a KTMC refinery at Sangdong, opened in 1961.

Sangdong mine's tungsten-bismuth ores contain recoverable molybdenum, about 3 percent of the scheelite by weight; molybdenum concentrates were recovered at the synthetic scheelite plant. Additional quantities of molybdenum came from small private mines.

NONMETALS

Cement.—Booming building activity in 1963 created a great shortage of cement and pushed imports sharply upwards. The government found it difficult to hold the price line, and cement prices tripled in some cases. Apparent consumption reached nearly 1.2 million tons during the year. The 5-year plan envisaged a cement consumption of 1.65 million tons by 1966.

Besides two existing plants, the 330,000-ton United Nations Korean Reconstruction Agency plant at Mungyong and the 300,000-ton Tangyang Cement Co. plant at Samchok, three others were under construction. These included two 400,000-ton plants, one at Sangyang in

Digitized by Google

Kangwon Province, and the other in Tangyang County, North Chungchong Province, both financed in part by West German credit; and a 150,000-ton plant, also in Tangyang County, financed through a U.S. Development Loan. Completion of the Sangyang plant was scheduled in December 1963, and the others were to be completed in April 1964. During 1963, Hyun-Dai Construction Co. placed a US$3.3 million contract with Allis-Chalmers International to modernize the Tangyang plant. Under consideration at yearend was whether to construct a sixth plant of 400,000-ton capacity or expand an existing plant by this amount. With all plans realized, total annual capacity would be about 2 million tons.

Fertilizers.—Two compound fertilizer plants were to be constructed, one at Ulsan and the other at Changhang, the cost to total an estimated US$100 million, according to agreements reached in October 1963, by the Korean Government and AID. The plants would require imported phosphate, since no domestic source was known. Production, equally divided between the two plants, would total 289,000 tons per year of contained nitrogen, phosphate, and potash compounds; the phosphate component would be 100,000 tons and the potash, 22,000 tons. In negotiating with foreign concerns for equipment and construction, priority was to be given to companies offering direct investment or credit assistance.

As a first step in plans to establish a 75,000-ton triple superphosphate plant, a Korean company (name unknown) was building a sulfuric acid plant on the east coast at Samchok. Scheduled for completion in January 1964, the plant was to produce 180 tons per day of 98 percent H_2SO_4. Inability of the seaport to handle oceangoing ships carrying phosphate rock and sulfur appeared to be a problem.

Korean fertilizer requirements were estimated for 1963, in terms of plant nutrients as follows: 200,565 tons nitrogen, 117,385 tons phosphorus (P_2O_5), and 29,110 tons potash (K_2O).

Fluorspar.—A custom fluorite-processing mill rated at 9,000 tons per year of concentrates grading plus 95 percent calcium fluoride was completed in March 1963 at Kumsan (Keum San), Cholla Pukto Province. Ores containing 50 percent fluorspar were supplied from a dozen or so nearby mines to this mill, and all output was exported. This operation produced less than one-fourth of South Korea's total fluorite in 1963.

Graphite.—South Korean graphite, mainly a low-quality amorphous mixture, generally occurs associated with anthracite and often is very similar to it. Production was primarily from four mines in 1963, chiefly by hand labor. The only important crystalline graphite operation was Sihŭng; its concentrator had a feed capacity of 200 tons per day. Its production in 1962 was reported at 183,879 tons of amorphous and 1,216 tons of crystalline graphite valued at US$2,010,000 and $147,000 respectively. Exports of graphite went mostly to Japan and possibly some of this material was exported under the classification for anthracite.

Digitized by Google

MINERAL FUELS

Coal.—Coal production, essentially all anthracite, increased in 1963 by 1.4 million tons, in accordance with the 5-year plan to boost output to 11.6 million tons in 1966. Of the 1963 production, 53 percent came from government-controlled Daihan Coal Corp. mines, with the following shares, in percent: Changsong, 22; Togye, 10; Hwasun, 8; Hambaek, 5; Unsong, 4; and Yongwol, 4. Anthracite was the country's main energy source for electric power, transportation, domestic heating, and fertilizer production. About 3 percent of the coal production was exported, mainly to Japan. Imported bituminous coal, mainly from Taiwan (coking) and Japan, was used in the iron and steel industry and for special purposes.

Inefficient rail transport in some mining areas limited movement of coal to markets, and coal shortages occurred despite rising production, particularly in industries depending on steam for power. Increased purchasing of bituminous coal from abroad was expected in order to meet growing demands, especially for the iron and steel industry.

The Korean Government was granted a US$9.5 million loan by AID in December 1963 for development work, to include the sinking of two deep shafts at the Changsong mine, Korea's largest and most important coal mine. Reserves at this deposit were estimated at 26 million tons.

Under the Mining Development Assistance Act of 1962, Daihan Coal Corp. took part in organizing small holdings in coal-mining areas into districts of potential economic size. As of May 31, 1963, six coal mine districts had been established—Rachon, Hwedong, Kuchol, Samchok, and Wongdong, all in the northeast, and Songju, in the west. Hwasun was proposed for a seventh district in the southwest.

Petroleum.—Consumption of petroleum products, all imported, was somewhat higher in 1963 than in 1962. The value in 1963 was estimated at US$31 million, excluding imports for military uses.

The Ministry of Commerce and Industry signed a US$16 million contract in October 1962 with Fluor Corp., California, for construction of a 35,000-barrel-per-day petroleum refinery at the Ulsan industrial site, following a favorable feasibility report by Universal Oil Products Co., a U.S. firm. The latter company signed a letter of intent with the Ministry in September 1962 to fulfill a US$783,000 contract covering design and supervision of construction. Construction progressed rapidly during 1963 and the plant, to be operated by the government-owned Korea Oil Co., was expected to be in full production by mid-March 1964.

The government in October 1963 approved terms of an agreement for a 25-percent equity investment by Gulf Oil Co. in the Korea Oil Co., under which Gulf was to release US$5 million in equity and US$6 million in loans to the company by the end of 1963.

The Mineral Industry of Laos

By K. P. Wang [1]

THE SMALL land-locked neutral Kingdom of Laos, with only two and a half million people, did not produce or consume any mineral product of significance by world standards during 1963. The nominal amounts of minerals extracted were of little consequence to the domestic economy.

Laos' premium mineral product has been a 50-percent grade tin concentrate produced for export. During the first half of 1963, tin concentrate output was about 650 metric tons, somewhat less than in 1962. The country's tin production in 1963 was about 0.2 percent of the world total and was valued at roughly US$700,000 which was equivalent to 0.5 percent of the gross national product.

As in earlier years, by far the most important mineral product consumed in 1963 was imported gasoline, roughly half of which was for aviation. All told, Laos acquired US$2 to 3 million worth of foreign refined petroleum products during 1962–63.

In 1963, extensive reserves of iron ore in Xieng Khouang Province were confirmed. The resource will be of little use to Laos unless it is developed for the export market; transport facilities through Vietnam probably would be required.

General conditions in 1963 were not conducive to mineral exploitation. The unstable political and security situation caused tin production from the existing mine to drop below the 1962 level and prevented the development of a second tin property. Also, a nearly completed cement plant in Thakhek may have to use local charcoal because coal cannot be obtained from a now "unsafe" area. The general economic situation was critical in 1963. Although a monetary stabilization program was initiated late in the year, there was no assurance that it would effectively curb runaway inflation. Under these circumstances, it was difficult to implement any effective mineral development program.

PRODUCTION

Tin is the only mineral product of Laos for which production statistics are available. Output of concentrates, and their approximate tin content have been as follows:

Year:	*Concentrates long tons*	*Metal content long tons*
1957	550	274
1958	601	301
1959	588	294
1960	765	383
1961	667	335
1962	709	367
1963	650	326

Digitized by Google

Laos also produced 1,000 to 2,000 tons of salt, small quantities of lime, and unreported quantities of construction quarry products.

TRADE

Tin was the leading export item of Laos in 1962–63. However, total mineral exports were only a fraction of mineral and metal imports.

During 1962, mineral and metal imports represented about 30 percent of the value of all imports by Laos. Refined petroleum occupied a major position among the mineral product imports, accounting for more than half the value. Metals, cement, and salt headed the lesser mineral imports.

TABLE 1.—Imports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal sources, 1962
Metals:[1]			
Aluminum	30	78	Japan 31; Thailand 32.
Copper	16	55	United States 49.
Iron	2,800	3,700	Japan 2,000; United States 700; Thailand 600.
Lead	14	38	Thailand 21; Hong Kong 15.
Nonmetals:

Total	do	326	369	Indonesia 347; United States 18.

[1] Estimated by the Bureau of Mines. Metallic ore imports are insignificant.

COMMODITY REVIEW

METALS

Iron Ore.—As of 1963, Laos reportedly had discovered two large high-grade iron deposits in Xieng Khouang Province. One was on a hilltop between the cities of Xieng Khouang and Phong Savan, with up to 1 billion tons of reserves, most of which can be mined by opencut methods; a second, of possibly similar magnitude, was 50 kilometers south of Xieng Khouang, according to French experts who examined both properties in a cursory manner. Systematic surveys on the first deposit were initiated late in 1963.

Tin.—The tin mining industry of Laos had a mediocre year in 1963, producing slightly less than in 1962. The only producer, the French concern of SEMMI (Société d'Étude et d'Exploitations Minières de l'Indochine) with an open pit mine at Phontiou in Savannakhet, Nam Patene Valley, still was not able to make any headway either in expanding production or improving product quality. The ore grade

Digitized by Google

at 0.2 to 0.8 percent tin is good; however, much of the tin-bearing mineral occurs in so fine a state that it cannot be recovered efficiently in the existing mill. In 1962, SEMMI exported 593 metric tons of 50-percent concentrate to the Penang smelter in Malaysia for smelting.

Adjoining Phontiou are Boneng and other properties that have not been worked since World War II. Apparently, extensive new reserves that can support an annual output of several thousand tons of mine tin were found in these properties during the last few years. A plan to exploit the newly discovered reserves by a joint French-Laotian tin mining company was not implemented in 1963 on account of the uneasy political situation.

Other.—During the last few years, SEMMI located lead, copper, and gold prospects in the Tchepone, Saravane, and Vientiane areas but again did no development on them in 1963 because of the general Laotian situation.

NONMETALS

Cement.—Laos has been intermittently building a 25,000-ton portland cement plant in the Thakhek area since 1954 with Swiss equipment and Swiss engineers. The latest word is that the plant was to have been substantially if not fully completed at the close of 1963.[2] Small quantities of lime made by burning wood were produced in 1963. The plant has five main units—lime burning, clay processing, kiln firing, clinker grinding, and gypsum blending. All raw materials will come from within 10 kilometers of the plant, except gypsum which is scheduled to be trucked in from extensive deposits at Dong Heng near Savannakhet. Coal from the now unsafe area of Saravane, if used in place of local charcoal, would make the plant more efficient. Local demand for cement has been met by imports from Thailand.

Salt.—One to two thousand tons of salt have been produced in Laos each year from brine operations (rock salt) in the Vientiane and Phong Saly areas. Although domestic production could be increased, imports supplement supplies of domestic origin at present. Laos imported 1,363 metric tons of salt in 1961 and 15,259 tons in 1962, all from Thailand.

MINERAL FUELS

Coal.—Internal security conditions apparently continued to be a factor in preventing development of several coal deposits, such as those north of Saravane.

Petroleum.—SEMMI was active in oil exploration near Vientiane and Thakhek. However, much more work needs to be done before the possibilities can be evaluated. Meanwhile, imports of refined oil products are relied upon to meet demand. As noted, aviation and motor gasoline are the main petroleum products consumed.

The Mineral Industry of Malaysia[1]

By J. M. West [2] and K. P. Wong [3]

MALAYSIA, the new Commonwealth nation established on September 16, 1963, through consolidation of the 11 States of Malaya, the Colony of Singapore, Sarawak, and Sabah (North Borneo), has a population of 10 million—three-fourths in Malaya and one-fifth in Singapore. One-half of the population is Chinese. Rubber, tin, and iron ore, solely from the Malayan Peninsula, traditionally have been the three most important products. [4]

Malaysia was the world's foremost tin producer in 1963 and provided slightly less than one-third of total mine production and about two-fifths of total smelter output. The country was the second largest iron ore producer in the Far East, surpassed only by mainland China. Bauxite output, from southern Malaya and Sarawak, was about 2 percent of the world total. A little crude oil and sizable quantities of refined oil were produced in the northern tip of Sarawak. The bulk of the crude came from nearby Brunei, still a sultanate independent of Malaysia. Brunei and Sarawak together supplied about 0.4 percent of the world's oil.

The mineral industry was responsible for about one-eighth of the US$2 billion gross national product estimated for Malaysia in 1963. Tin contributed two-thirds of the mineral output value, and iron ore about one-fourth; other mineral products included cement, oil, gold, and byproducts of tin such as columbite-tantalite, monazite, ilmenite, and zircon. Tin was marketed worldwide, with one-third going to the United States. Iron ore went exclusively to Japan.

Since tin contributes so heavily to Malaysia's national income and foreign exchange position, price fluctuations have always been of great concern. U.S. stockpile tin releases in 1963 had an initial stabilizing effect, but rising world demand subsequently forced prices up to US$1.29 per pound on December 19, 1963, the highest since June 1951. Tin resources appeared capable of supporting the 1962–63 output levels indefinitely. Tin recovery techniques were improved, and potential tin lands in national and State reservations were being released in 1963 for prospecting.

Two sizable iron mines and some smaller ones were operated during the year. Iron mining depended on Japanese demand; reductions of purchases and boosting of specifications by Japanese buyers were serious matters. In early 1963, a Japanese steel mission visited Kuala

[4] Owing to the change in political status, most 1963 figures apply to individual Commonwealth members rather than to Malaysia as a whole.

Digitized by Google

Lumpur to explain to Malayan iron producers why Japan wanted to reduce purchases and prices. The long-term outlook for new iron discoveries was considered only fair as of 1963; search was aided by aerial surveys but hampered by the dense jungle growth covering four-fifths of the country.

An oil refinery by Shell Refining Co., Ltd., at Port Dickson on the Malaccan Straits and an aluminum mill at Petaling Jaya near Kuala Lumpur were completed in 1963. Projects well underway included a tin smelter at Kulan near Kuala Lumpur which was being built to supply the Japanese market; steel mills at Prai near Penang and at Singapore; a second Port Dickson oil refinery by Esso Standard, Ltd.; and cement plants at Ipoh and Singapore. Another new refinery, by Socony Mobil Oil Co. at Singapore, was in the planning stage, with an operational date set tentatively for 1966. The Buket Ibam (Rompin) iron mine in Pahang was approaching full-scale production, and initial development began on the Bera Mukim iron deposit in southwestern Pahang.

GOVERNMENT POLICIES AND PROGRAMS

Malaysia, a relatively stable southeast Asian country, has a free enterprise system with minimum Government direction and a relatively favorable investment climate. Although the Government supports private enterprise, which provides the main source of capital, through the Economic Planning Unit, the Malayan Industrial Development, Ltd., and other agencies, it has taken the initiative to accelerate industrialization. One step is its "pioneer industry" program offering 5-year tax writeoffs and other inducements. Many subsidiary and wholly foreign-owned companies have been established in the absence of regulations limiting foreign ownership and employment.

Following consolidation, the Government continued with fair success the second 5-year plan (1961–65) of the old Federation of Malaya, which was aimed at increased private and public investment, industry diversification, rural development, and social improvements. Emphasis has been on establishing industrial estates such as at Singapore (Jurong), Kuala Lumpur (Petaling Jaya), Ipoh (Tasek), Johore Bahru, and Butterworth. The first stage (105,000 kilowatts) of the Malayan Central Electricity Board's Cameron Highlands hydroelectric project, north of Kuala Lumpur, was completed in 1963. The World Bank approved a loan for the second stage to provide an added 163,000 kilowatts of generating capacity by 1968. A thermal plant was completed at Johore Bahru, and another was under construction at Prai. Adequate electricity was essential to the mining industry, which consumed about one-third of the total power output.

The Government was forced to combat scattered insurgent fighting attributed to Indonesian-supported infiltrators. Indonesia announced an economic confrontation policy when Malaysia was formed and immediately ceased tin-ore shipments to Malayan smelters, rerouting ores to the Netherlands for treatment. Singapore, which derives about one-fourth of its gross domestic product from entrepôt trade, was faced with serious effects from the overall Indonesian trade ban.

Digitized by Google

With establishment of oil refineries at Port Dickson, the Malayan Government in 1963 levied excise duties on locally refined oil products equal to existing import duties so that petroleum revenues, a major source of income, would not be lost. It also revised in March 1963 the system of calculating tariff on imports of galvanized sheets from 10 percent ad valorem to 3 Malayan cents per square foot, about four times the old rate. Export duties continued on iron ore at 5 percent ad valorem and on tin at about 15 percent ad valorem plus excise tax.

The Malayan Government's Mineral Investigation Drilling Unit prospected for tin in Malaya reservations, completing studies of 56,000 acres in Perak and 5,000 acres in Selangor State. Removal of a prospecting ban on State and Federal reservations opened new areas for exploration.

The British Territories in Borneo Geological Survey Department became a branch of the Geological Survey, Malaysia, in September 1963. Detailed mineral information was given on the Sarawak, Brunei, and Sabah areas in the Department's 1962 annual report.[5]

PRODUCTION

Malaysia's mineral output in 1963 was valued at about US$250 million, about 5 percent higher than in 1962, owing mainly to increases in tin and iron-ore production and to higher tin prices. Tin and iron ore accounted for nine-tenths of the total production, the balance largely comprising cement, bauxite, and petroleum. Sarawak, with its Lutong oil refinery, minor oil production, and bauxite, was credited with about 6 percent of Malaysia's output.

Production of tin concentrate rose 2 percent and tin metal output rose 3 to 4 percent. Iron ore increased 12 percent. Bauxite output jumped 27 percent in Malaya, while in Sarawak it fell by nearly one-third, compared with 1962. Ilmenite and monazite recoveries (reported as exports) were higher in 1963 by 44 and 28 percent, respectively, and gold increased several thousand ounces. Comparing 1963 with 1959, output of tin rose by half, iron ore and cement by nearly 100 percent, and bauxite by one-sixth; gold production dropped radically, and the coal industry went out of business.

[1] All production from Malaya unless otherwise shown.
[2] Estimate.
[3] Includes metal smelted from imported tin concentrates.
[4] Processed at Lutong refinery; mostly from crude supplied by pipeline from Brunei.
[5] Includes reprocessing of sizable quantities of oil products imported in unfinished form.

TRADE

Malaysia's trade has two major components—the trade of Singapore, and the trade of what formerly was Malaya. The volume of Singapore's trade was slightly greater than that of Malaya in 1962–63. An important entrepôt center, Singapore consumes less than two-thirds of the goods it imports and serves as an entry for products destined for southern Malaya.

The value of mineral exports in 1962 exceeded that of mineral imports by about one-third. Virtually all of Malaysia's tin and iron ore are exported, providing by far the bulk of the mineral exports. Japan imported the iron ore, and the United States was the largest purchaser of tin, with imports of US$87 million in 1962. The pattern of tin and iron ore shipments was about the same in 1963. Singapore exported some $2 million worth of silver in 1962. This was possibly to cover trade deficits attributed to mainland China, which Malaysia recognizes.

TABLE 2.—Exports of metals and minerals in 1962

(Metric tons unless otherwise specified)

Commodity	1962	Principal destinations
MALAYA		
Metals:		
Bauxite—thousand tons	320	Japan 297.
Columbite-tantalite concentrate	65	United States 57.
Copper concentrate	1,250	All to Singapore.
Gold bullion—troy ounces	2,314	Singapore, 1,983.
Ilmenite concentrate	103,000	Japan 70,300; France 31,400.
Iron ore—thousand tons	6,540	Japan 6,490; Taiwan 50.
Iron and steel scrap	14,900	Japan 11,400.
Manganese ore	1,400	All to Japan.
Monazite concentrate	637	United States 465; Japan 172.
Tin:		
Ore—long tons	711	All to Singapore.
Metal—do	81,358	United States 34,481; Japan 10,318; Belgium-Luxembourg 5,855; Italy 4,735; India 4,476; France 4,363.
Slag and hardhead—do	911	All to United States.
Zircon concentrate	65	All to Japan.
SINGAPORE		
Metals:		
Aluminum, all forms	1,330	Malaya 1,190.
Copper, all forms	790	Malaya 525.
Iron and steel:		
Pig iron	1,280	Malaya 650; Brunei 620.
Steel bars and rods	27,600	Malaya 23,100.
Angles and shapes	7,300	Malaya 2,400.
Plates and sheets	[1] 23,100	Malaya 13,900.
Other semimanufactures	21,900	Malaya 17,300.
Lead, all forms	433	Denmark 274 (metal); Malaya 118 (products).
Silver—thousand troy ounces	1,892	All to United Kingdom.
Tin metal—long tons	1,409	Turkey 583; North Borneo 159; South Korea 158.
Zinc, all forms	992	Malaya 722.
Nonmetals: Cement (reexports)	78,000	Malaya 59,000.
Mineral fuels:		
Petroleum:		
Crude (reexports)—thousand tons	1,225	Sumatra 1,041.
Refinery products:		
Gasoline—do	[2] 962	Thailand 229; New Zealand 193; North Viet Nam 171; Malaya 137.
Kerosine—do	[3] 730	Thailand 134; Malaya 89; North Viet-Nam 65.
Distillate fuel oil—do	1,091	Malaya 262; Thailand 260; North Viet-Nam 187.
Residual fuel oil—do	1,075	Japan 470; Hong Kong 134; North Viet-Nam 119.
Lubricants—do	13	Malaya 9.
Other—do	5	Malaya 2.

[1] Includes 15,700 tons of galvanized sheets and 1,800 tons of tinplate.
[2] Includes 182,000 tons of aviation gasoline.
[3] Includes 308,000 tons of aviation jet fuel.

Malaysia's net mineral import for consumption in 1962 was estimated at US$170 million. Excluded from this figure was approximately $87 million in tin concentrate imported for smelting and $64 million in crude oil piped from Brunei into Sarawak for refining; both products were reexported after processing. The largest import item in 1962 was a net 3.6 million tons of oil (half crude and half refined) entering Singapore, two-thirds of which went into bunkering for ships and planes. Iron and steel products constituted the second-ranking import item for Malaysia.

COMMODITY REVIEW

METALS

Bauxite and Aluminum.—Both Malaya and Sarawak produced bauxite for export, mostly to Japan. Total output in 1963, valued at nearly US$4 million, was about three-fourths from Malaya and one-fourth from Sarawak. The production represented a 4-percent increase from that of 1962.

Malaya has two adjoining bauxite deposits, both on the Panggerang Peninsula in Johore State. Since closing of the Telok Ramunia mine of Ramunia Bauxite, Ltd., in 1961, Southeast Asia Bauxite, Ltd., with a new washing plant built in 1961–62 has been the sole producer.

In Sarawak, bauxite was mined at Sematan near Kuching by Sematan Bauxite, Ltd. Production has totaled nearly 1.1 million tons since commencement of operations in 1958. Mining has been confined to the Munggu Belian lease. Several deposits were under investigation in 1962–63, including the Buket Gebong, with an estimated 1.5 million tons in washed bauxite, and Tanjong Serabang, considered too low in grade for current use. Bauxite exports from Sarawak in 1962 totaled 232,000 metric tons valued at US$1.5 million, shipped to Japan (80 percent) and Taiwan (20 percent).

Malaysia's first aluminum rolling mill was opened in September 1963 at Petaling Jaya near Kuala Lumpur by Alcan Malayan Aluminium Co., Ltd., a subsidiary of Aluminium Co., Ltd., of Canada. The mill's capacity was rated at 2,000 metric tons per year of aluminum sheet. The company planned to use aluminum pig from Canada. Apparent consumption of aluminum in 1963 was estimated at 6,000 metric tons, of which about four-fifths was consumed in Malaya.

Gold.—Since closing of the Bukit Koman (Raub) lode mine in Pahang during 1961, virtually the only gold produced in Malaya has been the byproduct of tin mining (see Tin). Gold is mined on a small scale in Sarawak. Exploratory drilling in western Sarawak in 1963 at the foot of Gunong Krian Peak near Bau disclosed a marginal-grade gold-quartz orebody extending to a depth of nearly 300 feet; however, prospects of development were poor.

Iron Ore.—Iron ore, Malaysia's second-ranking mineral product, came from 2 sizable and about 20 small mines in 7 States of Malaya. Output in 1963, valued at about US$65 million, was one-eighth higher in tonnage than in 1962 and nearly double the 1959 level. The industry was fully dependent upon the market in Japan, which relied upon Malaya for one-fourth of its 1962–63 requirements. Despite available workable reserves for at least 10 years,[6] output levels may be cut back because of changes in Japanese demands.

About three-fourths of the country's 1963 iron ore output was produced by Eastern Mining & Metals, Ltd.; Eastern operated the Buket Besi (Dungan) mine, with an established capacity exceeding 3 million metric tons annually, and a subsidiary, Rompin Mining Co., operated the new Buket Ibam (Rompin) mine, which was expected to produce 1.5 million metric tons in 1963 and 3 million metric tons in 1964.

[6] Pearson, G. E. Malaya's Iron Future. Far Eastern Economic Review, v. 40, No. 8, June 6, 1963, pp. 552–553.

Digitized by Google

Small high-grade mines supplying the balance of iron ore output were troubled by low reserves, weak financing, and fluctuating Japanese quotas and grade requirements. Increased production in 1963 was due to renewed Japanese demand, following recovery from a 1962 recession in Japan, and to the opening of the Buket Ibam mine. Iron ore exports increased to 6.7 million metric tons valued at US$58.8 million in 1963.

The US$30 million Buket Ibam mine, largely U.S.-financed, represents probably the biggest single private investment in Malaya. Located deep in the jungle of Pahang State, it was connected in 1962 with the seaport of Jurong by a 50-mile railroad, permitting initial ore shipment. Ore reserves at Buket Ibam have been estimated at 20 million metric tons, but the mine has a peculiar quality control problem; although iron content is high, the ore contains troublesome nonferrous elements, such as copper, zinc, and bismuth. A nearby undeveloped deposit, Pasaki, containing 10 to 20 million additional tons of ore grading about 55 percent iron with little nonferrous impurity, was being explored in 1963 and was expected to provide ore for blending with that from Buket Ibam.

Buket Besi in Trengganu State supplied iron ore to the east coast port of Sura for shipment to Japan. Owing to foresight in installing a 3.5- to 4-million-ton-per-year concentrating plant in 1958 and to surprise development of additional reserves, the mine was expected to continue operating at least another 10 years at 1963 production rates. The deposit is unique because tin occurs both as an objectionable impurity and in separate tin-rich veins. Sufficient tin was recovered from portions of the deposit to make the mine the 12th largest tin producer in Malaya.

Investigations based on aeromagnetic surveys disclosed a potentially rich iron deposit estimated to contain at least 10 million tons of ore grading 66 to 68 percent iron in the Bera Mukim district, southwestern Pahang. The Malayan Government-sponsored National Investment Co., Ltd., acquired mining rights and was starting development jointly with a Japanese steel company to include a 25-mile jungle railway from the mine to Bahau, Negri Sembilan. The Perak State government issued 300-acre prospecting rights at another location, designated as magnetic anomaly 341, where a 10-million-ton iron deposit was indicated.

Iron and Steel.—Malaysia was slated to have several iron and steel plants operating in 1963–64.[7] The US$20 million Malayawata steel mill, a joint venture by Malayan interests and the Japanese Yawata Iron & Steel Co. at Prai, near Penang in northern Malaya, neared completion at yearend. The mill was scheduled to produce 120,000 metric tons of sponge iron and 60,000 metric tons of small bars annually. Sponge iron smelted from domestic ores was to be shipped to Japan for further smelting and returned in the form of ingots for final processing. The US$4 million National Iron & Steel Mill, to produce 70,000 metric tons of rolled products annually, was opened at the Jurong Industrial Estate, Singapore, in August 1963. A shipbreaking yard connected with the plant was under construction.

Digitized by Google

Similpan Steel Industries and Malaysia Steel Pipe Manufacturing Co., Ltd., both planned steel pipe and galvanizing plants at Singapore.

Net imports of iron and steel into Malaysia were estimated at 0.4 million metric tons in 1963, half from Japan and about 10 percent higher than in 1962. Sabah and Sarawak imported and consumed about 10,000 tons each. The Malaya-Singapore consumption was forecast to reach 1.2 million metric tons by 1980, compared with an estimated 306,000 metric tons in 1960.[8] Imports, comprising the bulk of consumption in 1960, were expected to provide only about 15 percent of requirements in 1980; the balance is to be supplied by rising domestic steel production.

In 1962, Singapore imported as much steel as all 11 Malaya States. About one-third was accounted for by entrepôt trade, mainly with Malaya. Singapore shipyards were responsible for a sizable consumption of steel plates and sheets, and there was a fair consumption of tinplate by local canneries. Apparent consumption of steel in the Singapore area was 100,000 to 150,000 metric tons in 1963.

Manganese.—A few thousand tons of manganese ore is produced yearly from deposits in Kelantan State, which were brought back into production in 1960 after being unworked since World War II.

Tin and Byproducts.—Malaya, with its famous Kinta Valley, is the world's foremost producer of tin. Mine-tin production in 1963 was 2 percent higher than in 1962 and slightly lower than the post-World War II peak of 62,295 long tons recorded in 1956. Deliveries of domestic ores to smelters totaled 60,879 tons of tin-in-concentrates in 1963, or 5 percent more than in 1962. However, imports declined by about 20 percent to 20,172 tons of contained tin, owing mainly to discontinuance of Indonesian shipments during the last quarter of 1963. Out of the 27,965 tons of tin concentrates (averaged 72-percent-tin content) imported in 1963, Indonesia provided 12,671 tons; Thailand 12,288 tons; Burma 1,996 tons; and Laos 554 tons.

Malaya's 1963 output of refined tin was about 3 to 4 percent more than in 1962. All output was from Malaya. Because of the decline of overall tin ore supply, substantial stocks had to be drawn upon in 1963, leaving only about 7,000 long tons of contained tin on hand at yearend. As in the past, all the tin metal produced was exported. According to company reports, Malaysia exported a record of 85,873 long tons in 1963: 35,615 tons to the United States, 20,883 tons to Europe, and 13,476 tons to Japan.

As of December 1963, 66 dredges and 643 other tin-mining units were in operation, employing nearly 34,000 workers in 9 of the 11 Malayan States. Dredges, mainly in Perak and Selangor, accounted for half the tin output; gravel pumps, two-fifths; lode mines, less than 5 percent; and hydraulic and opencast mines, the balance. Anglo-Oriental (Malaya) Ltd., with 13 subsidiary companies, worked 28 dredges and produced one-fourth of Malaya's mine tin. Pacific Tin was the only U.S. tin producer of any size. Berjuntai Tin Dredging, Ltd., was building a US$4 million dredge at its Batang Berjuntai property; the dredge will have a capacity of 500,000 cubic yards per month and a 135-foot digging depth.

[8] Yawata News (Tokyo). 20-Year Forecast of Southeast Asian Steel Demand. V. 2, No. 3, June 1963.

Digitized by Google

Two of the largest tin smelters of the world were in operation—the Penang smelter of Eastern Smelting Co., Ltd., subsidiary of Consolidated Tin Smelters, Ltd. (London), and, across the bay, the newer Butterworth smelter of Straits Tin Corp., Ltd. These two smelters, of nearly equal size, can smelt more than all the tin ore produced in southeast Asia. A 750-ton-per-month tin smelter was being built by Ishihara Sangyo Industrial Co. of Japan at Kulan near Kuala Lumpur for initial production in early 1964; this smelter is to supply the Japanese market.

World tin consumption was such that tin prices climbed 18 percent during 1963, despite release of 9,325 tons from the U.S. stockpile, and reached nearly US$1.30 per pound by the end of the year. Relatively high but unstable prices held back expansion plans.

Depletion of Malaya's richer tin reserves forced greater capital investment in large-tonnage, low-grade mining operations. Some relief was seen in the 1962 removal of Government bans on prospecting and mining on Malay Reservations, where rich finds were expected. In line with this policy, the Perak State government granted a mining lease to Société des Étains de Kinta on part of a railway reservation at Kampar, which contains US$25 million in tin.

Byproducts of tin mining included significant amounts of ilmenite, gold, columbite-tantalite, monazite, wolframite-scheelite, zircon, and copper concentrate. All byproducts except part of the gold were exported. Ilmenite went mainly to Japan and France, monazite and columbite-tantalite to the United States, and zircon to Japan. A few deposits in the Bakri area produced columbite-tantalite exceeding tin in value. Copper exported through Singapore was probably from the Sungei Lembing tin mine of Pahang Consolidated Co., Ltd. Tin slags containing about 5 percent combined columbium and tantalum oxides were shipped to the United States.

NONMETALS

Cement.—Malaysia's building industry enjoyed an unprecedented boom, particularly in Kuala Lumpur and Singapore, boosting cement consumption to an estimated 1 million metric tons in 1963. Apparent consumption during 1962 totaled 825,000 tons divided as follows, in tthousand tons: Malaya 515; Singapore 260; and Sabah and Sarawak 25 each. Cement consumption more than doubled in 1959–63; production was far short of demand, and black market prices rose to nearly twice the normal price of about US$1.30 per bag (about 110 lbs.). The great shortage of cement was met by imports, about two-thirds from Japan.

Cement production in 1963 came mostly from the 250,000-ton-rated-capacity Rawang plant of Malayan Cement, Ltd.; the balance presumably came from a small plant operated by Malayan Industrial & Mining Corp., Ltd., at Batu Caves. Both plants are near Kuala Lumpur. Singapore Cement Industrial Co., Inc., operated a clinker-grinding-and-packing plant in the Singapore harbor area, using cement imported from Onoda Cement Co. in Japan. Conversion of clinker to finished cement started in 1962, with output of 122,000 metric tons, rising to 194,000 tons in 1963.

Digitized by Google

The 500,000-ton Pan Malaysia Cement Works, a joint venture of Japan's Ishikawajima-Harima Co. and Malaya's Lew Yat Construction Co., was under construction at Kantan near Ipoh and due for completion in mid-1964. A subsidiary company, Pan-Malaysia Cement Works, secured a plant site at the Jurong Industrial Estate in Singapore and began work on a 250,000-ton cement plant due for completion in 1964; doubling of capacity was planned during the second year's operation of this plant.

MINERAL FUELS

Petroleum.—Expansion in petroleum refining was underway during 1963. Two refineries were being built at Port Dickson in Malaya, and another was being planned for Singapore. Oil refineries already in existence included Lutong in northern Sarawak and two in Singapore. These were operated by Shell Refining Co., Ltd., in Sarawak (45,000-barrel-per-day capacity) and by Shell and Maruzen Toyo Oil Co. in Singapore (about 15,000 and 30,000 barrels per day, respectively).

Shell Refining Co., Ltd., brought its US$17 million 20,000-barrel-per-day Port Dickson plant on stream in May 1963,[9] and Esso Standard, Ltd., was due to complete its US$15 million, 24,500-barrel plant, also at Port Dickson, in early 1964. Socony Mobil Oil Co. announced plans to complete construction of a US$13 million, 18,000-barrel refinery at the Jurong Industrial Estate in Singapore by 1966, through a new subsidiary, Mobil Refining Co. (Malaysia), Ltd.

Sarawak is Malaysia's only domestic source of crude oil, with less than 500,000 barrels produced annually. However, the small independent sultanate of Brunei, wedged between Sarawak and Sabah, is comparatively oil rich. During 1962, Brunei produced 28.5 million barrels (nearly 4 million metric tons) of crude oil valued at US$63.8 million, mainly from the Seria field; 645,000 barrels of natural gasoline; and 1,280 million cubic meters of natural gas. Its crude oil was piped to the Lutong area, partly for refining along with the Sarawak crude from Miri and partly (about half in 1962) for transshipment abroad. A little Brunei gas also went to Lutong and Miri. During 1962–63, the Brunei Shell Petroleum Co., Ltd., with exclusive prospecting rights in Brunei, concentrated exploration on offshore sites through the use of the Orient Explorer mobile drilling platform.

Malaysia apparently consumed 5.5 to 6 million metric tons (38 to 43 million barrels) of petroleum products in 1963, primarily the heavier refined oils. On an area basis in 1962, Singapore consumed about 3.5 million metric tons of oil; Malaya, 1.4 million tons; Sarawak, 300,000 tons; and Sabah, 100,000 tons. Actual consumption in Singapore, and therefore in all of Malaysia, was much lower because of large tonnages used for bunkering of foreign ships and planes. Malaysia's internal consumption of oil in 1963 was only 3 to 3.5 million tons. However, oil requirements were steadily rising, in line with increased industrial development and construction activities.

Digitized by Google

Total oil imports for the Malaysian area in 1962 exceeded 13 million metric tons. Sarawak took nearly 4 million tons of Brunei crude; it reexported half of this, two-thirds to Australia, and refined the rest. Nearly half of the refined oil was shipped out of Malaysia. Singapore imported about 5 million tons of refined petroleum (excluding that from Brunei via Sarawak), mainly from Indonesia, and reexported 3.1 million tons to Far East countries; Singapore also imported 3 million tons of crude oil, mainly from the Near East, and reexported at least 1.2 million tons, mostly to Indonesia. Malaya imported more than 1 million tons of petroleum products in 1962, primarily from Indonesia. Singapore's importance as an oil trading and transportation center is obvious.

The Mineral Industry of Mongolia

By K. P. Wang [1]

MONGOLIA or Outer Mongolia, a land-locked Alaska-sized nomad country with only 1 million people and much of its economic and industrial activity centered around the capital city of Ulan Bator, has never produced any mineral commodity of international significance, except for fluorspar which constituted about 2.5 percent of the 1963 world output. However, various other mineral commodities have been produced, and a number of resource projects are being constructed with the aid of other Communist countries, in an effort to industrialize. Coal has been the most significant mineral product, but production has been far short of potential from the viewpoint of reserves. Although Mongolia's coal reserves of billions of tons could support a much expanded production, geographical problems related to resources and markets have restricted mine development; only a few new coal mines have been developed in recent years and those completed have been small.

However, construction of an important industrial complex based on easily accessible local coal, iron ore, clays, limestone, and sand resources was well underway in 1963 [2] at Darkhan (Darhan) a railhead on the Ulan Bator-Peking Railroad. Much overburden was removed at the Sharyn Gol coalfield of the Darkhan complex during 1963, in preparation of eventual production of a million tons of coal yearly from a "50-year reserve." The U.S.S.R. was helping to build the coal mine, a 100,000-kilowatt powerplant, a 300,000-ton steel mill, and a glass plant; Czechoslovakia was assisting in construction of a 100,000- to 200,000-ton cement plant located southeast of the Burbantyn Plain; and Poland was aiding Mongolia in the erection of a large brick plant, planned primarily to produce ordinary white bricks, but also to manufacture fire bricks.

PRODUCTION

Mongolia's mineral production for 1959–63 is estimated. It is apparent that coal, petroleum, and nonmetallics are important. However, metals should not be ignored despite the lack of statistics, since several million dollars worth of such products might have been produced. All told, the country's mineral output value is very low, even by Far East standards.

TABLE 1.—Production of minerals[1]

(Metric tons)

Commodity	1959	1960	1961	1962	1963
Nonmetals:					
Alabaster (gypsum)	10,000	10,000	10,000	10,000	15,000
Fluorspar (fluorite)	34,000	40,300	38,000	40,000	53,000
Lime	8,000	10,000	13,000	21,000	25,000
Salt	5,000	6,100	7,000	8,000	8,000
Mineral fuels:					
Coal[2]	603,000	618,800	748,600	700,000	800,000
Petroleum:					
Crude oil	30,000	40,000	50,000	50,000	50,000
Refined oil:					
Gasoline	15,000	17,800	18,000	18,000	20,000
Diesel oil	5,000	7,040	7,280	7,300	8,000
Residual fuel oil	25,000	28,600	30,000	30,000	32,000

[1] All figures are estimated, except fluorspar for 1960–61, lime for 1961–62, salt for 1960, coal for 1959–61 gasoline for 1960, diesel fuel for 1960–61, and residual fuel oil for 1960. Other metals and nonmetals known to be produced include gold, lead-zinc, wolframite, clays, dolomite, limestone, and sand.
[2] Mainly so-called brown coal.

TRADE

Detailed data on Mongolian trade are lacking, but value of annual imports has been on the order of US$130 million to US$150 million and value of annual exports has been in the range of US$70 million to US$90 million. Most of Mongolia's trade has been with the U.S.S.R., and for this reason, in the absence of complete official Mongolian statistics, recorded Soviet imports from and exports to that country have been used as a measure of the country's trade. Only a few percent of Mongolian exports involve mineral products, and perhaps 15 percent of the country's imports consist of commodities in this group. Fluorspar has been Mongolia's only significant mineral export; Soviet imports from Mongolia totaled 37,500 tons in 1962 and 37,100 tons in 1961. Virtually negligible quantities of metallic ores and nonmetals from Mongolia have also been imported by the U.S.S.R. Recorded Soviet metal and mineral exports to Mongolia have consisted chiefly of iron and steel and mineral fuels.

TABLE 2.—Imports of metals and minerals from the U.S.S.R.

(Metric tons)

Commodity	1961	1962	Commodity	1961	1962
Metals:			Mineral fuels—Continued		
Iron and steel:			Coke	1,000	1,000
Pig iron	800	1,000	Petroleum:		
Rolled steel	12,900	22,500	Crude	24,300	30,900
Iron and steel pipes	4,900	4,900	Refinery products:		
Wires and nails	1,900	2,500	Gasoline	62,500	75,400
Nonferrous metals	90	140	Diesel fuel	47,500	48,000
Mineral fuels:			Lubricants	7,800	9,600
Bituminous coal	29,000	180,000	Other	600	800

COMMODITY REVIEW

METALS

In 1963, the country's production of wolfram concentrate, from the Ih Hairhan and Burentsogt mines, probably totaled about 50 to 100 tons. Gold has been a traditional product, but no output statistics are available. Some lead-zinc ore was produced for export.

NONMETALS

Fluorspar.—According to the Mongolians,[3] output of fluorspar, presumably from the Berkh or Berhiyn mine 70 kilometers east of Ondor Haan, increased 36 percent in 1963 compared with 1962, which means that the 50,000-ton level was exceeded and roughly half of the ultimate target achieved. Virtually all Mongolian fluorspar has been exported to the Soviet Union.

Other Nonmetals.—A 10,000-ton per annum alabaster plant in the Dundgob Aymak was placed in operation in 1963; this is the second alabaster plant in Mongolia. The Tsagaan Bula lime plant in the Darkhan area was expanded during the year.

Sizable tonnages of clay, sand, dolomite, and salt were produced for domestic consumption.

MINERAL FUELS

Coal.—Coal,[4] mostly so-called 4,900-kilocalorie brown coal from the Nalaikha mine 35 kilometers east of Ulan Bator, has been the country's foremost exploited mineral resource, but Mongolia's coal production has not satisfied the demand by the power and other industries. Thus, imports have been necessary, as for example the 180,000 tons of bituminous coal obtained from the Soviet Union in 1962.

Petroleum.—As of 1963 Mongolia's small petroleum industry[5] was still far from achieving the basic objective of self-sufficiency. A Soviet-built refinery, turned over to the Mongolians in 1957, is in existence at Dzuun Bayan near the Sayn Shanda oilfield in the Gobi Desert. With an annual capacity of possibly 100,000 metric tons of crude oil this refinery may have processed approximately 30,000 tons of Soviet crude and 50,000 tons of local crude oil during 1963. In recent years, the deficiency in refined petroleum products has been met by annual imports of 110,000 to 140,000 tons from the Soviet Union.

The Mineral Industry of Pakistan

By L. Nahai [1]

PAKISTAN'S production of each of the major mineral fuels—coal, petroleum, and natural gas—increased in 1963, continuing the trend of the past several years. The country's scrap-based steel plants also showed production gains over 1962 output, as did the cement plants; but neither of these segments of the mineral industry was able to meet Pakistani requirements for their products, and significant imports of these commodities continued.

Pakistan did not contribute significantly to other nations' supplies of minerals. Production of chromite, Pakistan's foremost (and only significant) mineral export commodity has not exceeded 1 percent of the world total and in 1963 declined by nearly one-third from output in 1962 owing to poor market conditions.

The total value of crude minerals produced in 1962 (the last year for which reasonably complete data are available) totaled about US$47 million. The value of cement output raised the total to about US$90 million. Value added by the steel rerolling industry altered this figure only slightly. The contribution of the mineral industry to the gross national product (GNP) was quite small; mineral and mineral product output value was about 1.1 percent of the GNP. Of the total value of mineral and mineral product output in 1962, cement accounted for about 48 percent, petroleum for about 20 percent, coal for about 14 percent, natural gas for about 11 percent, and all other commodities for about 7 percent.

Pakistan is not well endowed with mineral resources. Except for natural gas, known deposits are almost entirely in West Pakistan. Natural gas reserves of West and East Pakistan, estimated to total at least 10,430,000 million cubic feet, are Pakistan's most important mineral asset. The total reserve of coal in all categories of depth, thickness, and reliability is estimated to be about 150 million tons. Coal reserves are in three areas of West Pakistan: Salt-Range-Trans Indus, Baluchistan, and Sind. Much of the coal is subbituminous, and relatively high in ash and sulfur; practically none is of metallurgical grade.

Iron formations in Pakistan are estimated to contain about 400 million tons of ore, however, all but 1 percent of the total is apparently low-grade. Nearly 75 percent of the total is in the sedimentary deposits in the Kalabagh-Makarwal area. The low iron content, complex mineralogy and nonamenability to beneficiation of the iron-bearing material here militate against its use as an iron ore. Sedimentary deposits of Hazara are similarly low grade.

[1] Near East-South Asia specialist, Division of International Activities.

Digitized by Google

Occurrences of antimony, copper, lead, and some other metals are known but owing to one or more unfavorable factors such as poor location, low grade, and presence of deleterious minerals, only a few have been worked; most are not commercial deposits at the present time.

Pakistan's nonmetallic mineral resource supply position is somewhat better. Limestone, gypsum, and salt are abundant in West Pakistan. Deposits of barite, bentonite, celestite, fuller's earth, magnesite, marble, and glass sand also are known in West Pakistan and have been exploited to some extent. However, resources of a number of nonmetallic minerals such as asbestos, boron minerals, fluorspar, phosphate rock, potash, and sulfur are inadequate or nonexistent.

Lack of building stones and aggregate materials is serious in East Pakistan.

Pakistan's second 5-year plan for economic development (July 1960 to July 1965) reportedly will include the expenditure of the equivalent of US$4,830 million of which US$210 million will be allotted to fuels and minerals, distributed approximately as follows: Petroleum exploration and transmission and distribution of natural gas, US$170 million; development of coal mines and increased coal production, US$25 million; exploration and development of other minerals, over US$1 million; and Geological Survey of Pakistan, about US$14 million. The consortium of governments and institutions interested in development assistance to Pakistan has pledged, subject as appropriate to legislative action or other necessary authorization, US$425 million for the fourth year of the plan, which began July 1, 1963. Previous commitments totaled US$1,175 million.

Although accomplishments in the first 3 years of the plan related to fuels and minerals cannot be fully assessed, industrial and urban construction and water and power schemes in the Indus Basin have increased demand for raw materials of the building industry. Increased industrial production in 1963, particularly in the private sector, has resulted in a record rate of natural gas consumption. Development of the paint and chemical industry has influenced production of some nonmetallic minerals such as barite, sulfur, salt, and evaporite deposits. Exploration and development has been accelerated by foreign technical assistance programs. A staff of U.S. geologists and engineers continued to operate under a 5-year Mineral Exploration and Development Project financed by the U.S. Agency for International Development (AID). Foreign private companies and Soviet Government technicians carried out petroleum exploration projects.

PRODUCTION

For the majority of mineral commodities produced in Pakistan no significant trend is apparent; however, substantial increases in the output of coal, natural gas, crude petroleum, petroleum products, limestone, cement, and rock salt are noted between 1959 and 1963. The near doubling of petroleum product output in 1962 compared with that of previous years resulted from operation of a new refinery in Karachi. The rise in natural gas production was the principal factor in increas-

Digitized by Google

ing the index of overall mineral production in the latter half of 1962 to 140, compared with 100 in 1959–60.

Pakistan does not have any primary metal producing industry except for a small antimony operation in Swat. Reported crude steel output was from small electric furnaces using imported and local scrap. Imported ingots and scrap continued to be rolled into bars, shapes, hoops, and wire in some 100 steel mills with 100,000 to 150,000 tons total annual capacity, but data on total output are not recorded.

TABLE 1.—Production of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963

Total do	2,191	2,313	2,642	4,985	(2)

[1] Except where otherwise noted, output is all from West Pakistan.
[2] Data not available.
[3] Estimate.
[4] Revised figure; does not agree with that reported in Commodity Chapter of v. I or v. II; revised data not available in time for inclusion in other volume.
[5] Officially reported as iron ore, but consists of test lots obtained during exploration which were not used to recover iron.
[6] Includes East Pakistan as follows in metric tons: Ingot steel; 162, 139, 1963, 2,118.
[7] Includes East Pakistan as follows in thousand metric tons: 1959, 44, 1960, 70, 1961, 96, 1962, 90, 1963, 77.
[8] Includes East Pakistan.

TRADE

Pakistan's principal mineral export has been chromite which has been exported at rates varying from about 10,000 to 35,000 tons during

Digitized by Google

1955–61. Owing to market conditions, very little chromite was exported in 1963.

Pakistan has been dependent on imports to supply almost all requirements for iron and steel, nonferrous metals, and many industrial minerals such as abrasives, asbestos, and fertilizer raw materials. A substantial part of its coal, petroleum, and sulfur requirements also have been imported. In 1960–61 the total value of these imports was approximately US$255 million (nearly 26 percent of total imports) distributed as follows: Iron and steel, US$110 million; petroleum, US$94 million; nonferrous metals, US$21 million; coal and coke, US$16 million; construction materials, US$9 million; and ores and minerals, US$4 million.

The total for iron and steel may include some manufactures, but probably the bulk of the imports comprised rolled steel products such as beams, rails, wires, and construction steels. Among the nonferrous metals, in terms of value, aluminum ranked first (US$9,762,000) followed by copper (US$6,533,000).

TABLE 2.—Exports of selected metals and minerals

(Metric tons unless otherwise specified)

Commodity [1]	1961	1962 [2]	Principal destinations, 1961
Metals:			
Aluminum ore (bauxite)	127	(3)	All to Japan.
Chromite	13,150	9,803	United Kingdom 7,343; Japan 5,906.
Iron and steel:			
Iron ore [4]	559	(3)	All to Japan.
Scrap	2,737	(3)	Mainly to Japan.
Lead ore and concentrate	127	(3)	All to Japan.
Nonmetals:			
Aragonite	25	(3)	All to Italy.
Cement	35,801	(3)	India 32,327; Afghanistan 3,473.
Salt, all types	130,119	90,738	Japan 111,475; Ceylon 9,918; Spain 6,503.
Stone, worked and unworked:			
Marble	1,853	(3)	Italy 1,631.
Other	310	(3)	Italy 269.
Mineral fuel:			
Petroleum refinery products:			
Kerosine---42-gallon barrels	100	(3)	All to Afghanistan.
Distillate fuel oil---do	111	(3)	Do.

[1] In addition to items listed, Pakistan exports small quantities of a wide variety of metals and minerals in semifabricated forms; quantitative data for these exports are not given, but in 1961 they were valued at about PRs750,000 in total, compared to a value for items listed here of PRs6,952,844; of which salt accounted for 30 percent, chromite for 24 percent, marble for 16 percent, and cement 12 percent. 1 PRs equals US$0.21.

[3] Data not available.

[4] Test shipments.

Source: Except as noted, official foreign trade returns of Pakistan.

In 1960–61 suppliers of iron and steel to Pakistan, ranked in order of importance by value of material supplied were Japan, Belgium-Luxembourg, West Germany, United Kingdom, and United States. Nearly half of the nonferrous metals originated from Canada and United Kingdom. Iran supplied a little less than half of the petroleum imports with Saudi Arabia, United States, and Bahrain each supplying about 10 percent of the imports. Coal imports were largely from India. As a result of a number of nonproject, low-interest, long-term loans which U.S. Agency for International Development has made to Pakistan, the relative share of Pakistan's metal imports sup-

Digitized by Google

plied by the United States has increased since 1960–61. The latest loan was for US$70.5 million, and was agreed upon in September 1963. Of this total, US$46.5 million has been allocated for iron and steel industry development.

TABLE 3.—Imports of selected metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1960	1961	1962
Metals:

COMMODITY REVIEW

METALS

Iron and Steel.—The Government of Pakistan plans to establish a steel plant in each province, and the one for East Pakistan approached realization in 1963. Kobe Steelworks, Ltd. of Japan bid successfully

Digitized by Google

to build a 150,000-ton-ingot-capacity plant in Chittagong to operate on imported pig iron and scrap. The plant will cost US$61 million, including US$38 million foreign exchange. In September the Governments of Pakistan and Japan signed a US$30 million loan agreement, and the Chittagong steel plant was one of the projects to be financed under the loan. Local currency requirements will be met by East Pakistan Industrial & Development Corp., an agency of Government of Pakistan. Construction was to begin in late 1963, and was tentatively planned for completion in 1966. Principal facilities of the plant and annual production targets, in metric tons, are as follows: Three open-hearth furnaces, 150,000 tons of ingots; three bloom, billet, and sheet-bar mills, 129,000 tons of billets and sheet bars; one bar mill, 43,000 to 45,000 tons of bars; one sheet mill, 50,000 tons of sheets; and one plate mill, 15,000 tons of plates. The plant will require the following raw materials which, except for limestone, dolomite, and fluorspar obtainable from West Pakistan, would have to be imported:

Commodity	Quantity (metric tons)	Commodity	Quantity (metric tons)
Pig iron	70,500	Ferroalloy	2,085
Steel scrap	62,500	Refractory bricks	6,024
Iron ore	600	Dolomite	5,250
Limestone	30,000	Rolls	719
Fluorspar	225	Fuel oil	40,000

The plan for the establishment of a steel plant in Karachi with 350,000 tons steel ingot capacity per year was in abeyance at yearend pending a feasibility study for the Export-Import Bank which received a US$67 million loan application for financing the steel mill. The design and construction of this plant, if approved, will be carried out by Swindell-Dressler Corp. & Associates (SDA), a consortium of five American companies that was selected in 1961 by the Government of Pakistan after international competition. The member companies of the consortium are expected to invest in the plant. SDA and a consortium of seven Pakistani industrialists have organized National Steel of Pakistan, which will be the owner of the plant. This company has authorized capital equivalent to US$105 million.

Current consumption of iron and steel is estimated at 350,000 tons per year and is predicted to exceed 500,000 tons by 1965. These requirements have been met largely by imports of rolled products and ingots for rerolling in Pakistan. Less than 15,000 tons of ingot steel was produced in Pakistan in 1963, all from scrap melting. Ingot imports increased 12 times between 1950 and 1960, while imports of all categories of iron and steel increased 2.5 times in the same period, indicating the enhanced importance of the rerolling industry in supply of iron and steel products.

Although very limited quantities of Pakistani iron-bearing materials continued to be produced for metallurgical testing, there has been no indication that commercial mining may be expected in the near future, if at all.

Other Metals.—Pakistan does not produce nonferrous metals from domestic or imported ores, except for a small tonnage of antimony.

Digitized by Google

Similarly, there are no plants for refining and rolling of nonferrous metals, although small shops make brass and aluminum sheets and circles for utensils. In absence of other information, import statistics provide the best indication to consumption and size of the market for principal nonferrous metals.

Pakistan's 1963 chromite output was obtained from workings near Hindubagh, about 100 kilometers northeast of Quetta. Poor market conditions resulted in a pronounced decline in output between 1962 and 1963, and by yearend productive operations were reportedly shut down or nearly so. Mine production of other metals was inconsequential.

NONMETALS

Cement.—In spite of record production, cement shortage was experienced in both Provinces, particularly in East Pakistan. In September barter agreements were signed for 100,000 tons of cement from the U.S.S.R., 70,000 tons from Poland, and 100,000 tons from mainland China in exchange for Pakistani jute and other products. In West Pakistan a fourth kiln was fired in the Zeal-Pak plant near Hyderabad, and construction of three plants in the private sector continued. These plants, located at Gharibwal, Manghoopir, and Hattar, will add 1,020,000 tons to the current 1,500,000-ton annual capacity.

Gypsum.—On the basis of a report by a Japanese survey team, the Pakistan Industrial Credit & Investment Corp., an organization established in 1957 as an industrial development bank to assist the private industry, has approved plans for Pakistan's first gypsum board factory, to be located between Lahore and Rawalpindi. Japan will provide the necessary foreign exchange. Ample gypsum is available in the Salt Range near the plant location.

Sulfur.—To assist a local firm which started producing sulfur in 1962, the Government in 1963 banned import of sulfur for the match, rubber, and sugar industries, but acid and other plants were permitted to continue imports. Current requirements are estimated at about 7,000 tons per year, 80 percent of which is used by the acid industry. Therefore, the ban on imports does not affect the bulk of imports. Consumption is estimated to triple by 1964 to 65 tons per day.

MINERAL FUELS

Pakistan's energy requirements were met by coal, petroleum, natural gas, hydroelectric power, and animal and agricultural waste. Total production of energy in 1961 from commercial sources was 2.54 million tons of standard coal equivalent. Consumption was 6.54 million tons; domestic output supplied 39.4 percent of the commercial energy. Petroleum and natural gas were the principal sources of domestically produced energy.

Atomic energy is not yet produced in Pakistan, but tenders were called for the construction of a megawatt atomic energy plant at Ruppur near Ishurdi in East Pakistan. A reactor-laboratory complex is also being built in Islamabad.

Coal.—Production was obtained from the Salt Range and Makarwal fields in Sargodha Division, the Sor Range-Dagari, Khost-Sharigh,

Digitized by Google

Mach and Pir Ismail fields in Quetta and Kalat Divisions, and from Meting-Jhimpir and Lakhra fields in Hyderabad Division. The bulk of the Makarwal production is used for generation of synthesis gas for the Daud Khel ammonium sulphate fertilizer plant.

Diamond drilling by the Geological Survey of Pakistan in the Lakhra anticline during 1961–63 proved the existence of a coalbed 0.8 to 2.5 meters thick, commonly at depths less than 45 meters, with a reserve of 130 million tons.

A drilling program financed by the United Nations Special Fund struck a 30-centimeter seam of coal at 913 meters, a 1.8-meter seam at 940 meters, a 6-meter seam at 1,000 meters, and a 20-meter seam at a further but unspecified depth. The site of the drilling is near the village of Jaipurnat, in the Bogra district, 10 kilometers from the Indian border. Apparently these seams are related to seams of the Gondwana field in India.

It is believed that in 1963 the West Pakistan Industrial Development Corp. signed an agreement with Lurgi to establish a low-temperature carbonization plant in Quetta. The plant, using a Lurgi process, will produce about 40,000 tons of coke briquets and 17,000 tons of char sinter from Sor Range, Dagaré, and Sharigh coal fines.

Natural Gas.—Production from the Sui Gasfield during 1963 was at a daily rate of 85 million cubic feet—55 million to the Karachi pipeline and 30 million to the Multan line. This field, discovered and developed by Pakistan Petroleum, Ltd., is the largest in West Pakistan; with a reserve of 5,000,000 million cubic feet, it has been in production since 1955. A loan application for US$70 million was submitted by the Sui-Northern Gas Pipeline Co. (a joint company of Burmah Oil Co. and West Pakistan Industrial & Development Corp.) to the International Bank for Reconstruction and Development to finance extension of the Sui-Multan line beyond Multan by addition of 580 kilometers of trunk line and 177 kilometers of distribution line. These lines would supply gas to Lyallpur, Lahore, Gharibwal, Rawalpindi, Wah, and the new capital of Islamabad. As of yearend 1963, the application had not been acted upon.

The Mari field of Esso Standard Eastern, Inc., also in West Pakistan, is not being utilized.

In East Pakistan the Chhatak and Sylhet fields of Pakistan Petroleum, Ltd., are currently exploited. These fields have reserves of 20,000 and 280,000 million cubic feet of gas and supply natural gas to a cement plant and the Fenchuganj fertilizer plant, respectively. Pakistan Shell Co. has also discovered three fields within 40 kilometers of one another: Rashidpur (740,000 million cubic feet reserves); Kailas Tila, and Brahmanbaria. The latter, discovered in late 1962, is considered to be a large field and may be utilized for production of power, petrochemicals, and fertilizers.

Petroleum.—Domestic output of crude petroleum in 1963 was equal to about 15 percent of the total needed to produce Pakistan's refinery product requirements. Petroleum exploration was carried out by the Oil & Gas Development Corp., an agency of the Government of Pakistan, assisted by the Soviet Union and by private companies. The Soviet aid, in form of equipment and services, was supplied under a loan equivalent to US$30 million granted by the Soviet Union to

Digitized by Google

Pakistan in March 1961 for oil exploration. The loan is to be paid within 12 years and bears 2.5 percent interest.

Activity of the Pakistan-Soviet teams in West Pakistan was in the Potwar plateau area and had the objective of developing information on the complex geology of the area. The Oil & Gas Development Corp. announced that Chharat, 40 kilometers west of Rawalpindi, was selected for drilling, but at yearend actual drilling was not reported. In East Pakistan, five Pakistan-Soviet parties were reported to be active, and drilling in this province was expected in early 1964, probably near Cox's Bazaar.

Pakistan Sun Oil Co. completed offshore seismic survey in the Indus delta region, and Pakistan Petroleum, Ltd. completed its survey in Sanghar area of West Pakistan. After abandoning its test well in Baluchistan with no indication of commercially exploitable gas or oil, Tidewater Oil Co. surrendered its oil exploration license. Pakistan-Shell activity was in the Brahmanbaria area of East Pakistan where the company has discovered three gasfields.

Pakistan Oilfields, Ltd. (70 percent Attock Oil Co. and 30 percent Government of Pakistan and private investors) continued its operation in Pakistan's only producing fields of Dhulian, Balkassar, Joya Mair, and Khaur fields. The bulk of production was obtained from the first two fields. Balkassar was operated jointly with Pakistan Petroleum, Ltd. (70 percent Burmah Oil Co. and 30 percent Government of Pakistan and Pakistani private investors). These two companies were drilling a deep test well, Chak Beli Khan 3, 22 miles southwest of Rawalpindi.

The most significant development in petroleum refining was the announcement in December 1962 of an agreement between the Government of Pakistan and Regie Autonome des Petroles (RAP.) of France to build a refinery in Chittagong with 70 percent capital participation by Pakistanis and 30 percent by RAP. The daily throughput capacity of the refinery will be 20,000 barrels expandable to 30,000 barrels. The refinery's cost is estimated at US$14.1 million (US$9.1 million to be foreign exchange) and it is due to come on stream in 1965.

In September 1963 National Refinery, Ltd., a Pakistani firm managed by Amin Agencies, and the American International Oil Co. signed an agreement for the construction of a US$17 million refinery in Karachi to produce principally bitumen, lubricating oils, jute batching oil, light diesel oil, and small quantities of wax and weed killers. When completed in 1966, the installation will handle 8,000 to 10,000 barrels of crude oil per day. In return for providing technical assistance to the refinery and helping to arrange a US$10 million loan through the Bank of America, the American International Oil Co. will supply crude to the refinery.

Pakistan's largest existing refinery is also in Karachi. This refinery, owned by Pakistan Refinery, Ltd., had a throughput of 30,000 barrels per day. It was officially opened in November 1962 and was built by Esso, Shell, Caltex, and Burmah Oil Co. who together supplied 60 percent of the capital while private Pakistani capital provided the remaining 40 percent. At yearend, it was announced that plans had been laid for expansion of capacity to 42,000 barrels per day.

The Mineral Industry of the Philippines

By K. P. Wang [1]

THE PHILIPPINE production of crude minerals amounted to about US$110 million or roughly 2.7 percent of the gross national product in 1963. Half of the output, including most of the base metal ores, was exported, earning 7 to 8 percent of the country's foreign exchange. In terms of value, copper was the leading product and gold was the second. Virtually all of the chromite is produced for export and, in terms of volume, the shipments of iron ore rank first and chromite second among mineral exports.

Among the diversified mineral products extracted in the Philippines, only refractory chromite is of major significance by international standards. In 1963 the country was, however, the leading gold producer and the third-ranking mine copper producer in Asia. Philippine outputs of copper, gold, and mercury represent about 1 percent of the world total in each case.

The Philippines is a favorable mineral province, except for fuels, and has had a long tradition in mining. The mining industry of the country has been established and expanded primarily by foreign capital and technology, largely from the United States and Japan. However, in recent years, Filipinos have participated to an increasing degree in mineral development.

There is increasing sophistication in the type of mineral commodities produced, such as the recovery of more pyrite for making fertilizers, extraction of molybdenum and zinc from copper and gold ores, and plans to establish integrated steel, refined copper, and more ferroalloy facilities. Many mineral concerns also are branching into other lines of industrial endeavor.

The reserve position for refractory chromite was improved. During 1963, Philippine Iron Mines Inc. made considerable headway on a new concentrator. Two new cement plants—Teresa on Luzon and Iligan on Mindanao—were under construction. Two additional oil refineries came into being in 1962–63: Shell's 25,000-barrel-per-day plant and Filoil's 10,000- to 15,000-barrel plant.

GOVERNMENT POLICIES AND PROGRAMS

The economy of the Philippines, a country of 30 million people, showed much improvement in 1963 compared with 1962. The 1963–67

[1] Chief specialist, East Europe–Far East, Division of International Activities.

Digitized by Google

5-year socio-economic development plan was initiated. Decontrol of the peso (started in January 1962) continued to have a stimulating effect on economic growth and helped to stabilize the general environment for establishing industries. The upturn in economic activity was supported by greater willingness of Japanese and U.S. firms to develop Philippine enterprise through investment and commercial contracts.

The Government initiated the 1963–67 5-year development plan based primarily on private enterprise. This plan envisages US$6 billion in fixed investments, including roughly 3 percent for the fairly well established mining industry and 15 percent for the metal and metal products industry. This differential should narrow the gap between these two industries.

A new foreign investments bill was introduced in Congress in 1963. It reflected the Philippine preference for joint ventures with the necessary incentives in the form of exemptions from capital gains tax, reduction of income tax, tax-free importation of equipment, deductible losses in the first 3 years of operations, accelerated depreciation losses, and loan preferences from the Development Bank of the Philippines. According to the Filipinos, capital and profits can be freely remitted and foreign investors will have an informal voice in formulation of national economic policies.

A serious effort was made in 1963 to modify the Corporation Law, which limits capital participation by any firm in mining enterprises. The legislation introduced would allow any legal body to own 40 percent of three or four mining corporations. Furthermore, it was proposed that, although a U.S. mining company could have only one mining subsidiary in the Philippines, this subsidiary would have the same rights as other Philippine mining companies. The intent of the legislation is to attract more Filipino and U.S. mining investment capital.

Philippine Government grants of special privileges to U.S. citizens will be effective only until 1974, but other nationals such as the Japanese can hold minority interest in Philippine firms. The substantial Japanese contribution to Philippine mineral development, motivated by the need to acquire raw materials, has been principally in the form of technical advice, equipment, loans, and advance of funds for future deliveries. Mitsubishi Metal, Mitsui Mining & Smelting, and Nippon Mining had, for example, extended significant assistance during 1962–63. Thus, the Japanese have not been seriously restrained by the Corporation Law.

Government mineral officials are acutely aware of resource development problems, but some Filipinos consider ore reserves in the ground as valuable assets that should only be exploited by citizens. An attempt was made in 1963 to make the Nickel Bill (concerning Surigao laterites) more atractive to foreign investors, but it was not successful.

The effect of the decontrol (of the peso exchange rate) on the Philippine mining enterprise became clearer in 1963. Overall, the change favored the exporter and dollar earner, that is, most of the mineral concerns. Although costs of imported equipment and labor rose, the increased values obtained for the minerals exported more than compensated for the rise. Decontrolled, 20 percent of mineral export

Digitized by Google

receipts had to be turned over to the Philippine Central Bank at the rate of 2 pesos to the dollar whereas the rest was realized at the free market rate of 3.90 pesos to the dollar.

PRODUCTION

The value of crude mineral production in 1963 is estimated at about US$110 million. In 1962 it totaled about US$105 million and was equivalent to about 2.7 percent of the gross national product evaluated at US$3,900 million. The value of crude mineral production cited covers primarily mine output and does not include the added value derived from processing ores and other mineral products.

Output of many mineral products of the Philippines was somewhat lower in 1963 than in 1962; gold, silver, iron ore, chromite, cement, manganese ore, and coal among other commodities showed declines of varying magnitude. Of major mineral products, only copper ore and pyrite showed production gains.

The gain in copper output was attributable to expansion programs and other new projects, some of which were still underway at yearend. The gold output decline occurred in spite of price supports. Chromite producers were in a depressed condition because of sluggish world demand. The sharp decline in manganese output resulted from difficulties in upgrading the ore. The search for oil yielded no worthwhile results in 1963. Increases in refined oil production from imported crude during 1959–62 reflected increasing Philippine consumption.

Distillate fuel oil do	1,736	1,896	4,083	4,893	5,872
Residual fuel oil do	2,817	2,894	4,873	5,942	7,561
Refinery fuel (including losses) do	402	588	892	1,005	1,374
Other products do	14	462	429	1,455	1,545
Total do	8,942	10,091	18,484	22,337	27,521

[1] Data not available.
[2] Estimate.
[3] Includes zinc content of copper-zinc concentrates containing 46 percent zinc and 3 percent copper.

TRADE

Mineral trade, particularly in base metal ore exports, is fundamental to the Philippine economy. Japan was again by far the leading market in 1963 and the United States was second. Philippine mineral exports were essentially controlled by metal prices and demand in these two

Digitized by Google

countries. Japan recovered from its 1962 recession in mid-1963 and started to buy more Philippine raw materals again. Japanese demand for nonferrous ores has been particularly steady, but purchases of Philippine ferrous ores are carefully scrutinized according to quality and price considerations in comparison with supplies from other sources. The United States regularly takes only a small portion of Philippine copper, specifically mine copper from Lepanto that is shipped to the Tacoma, Wash., smelter. The Philippines has long been the principal supplier of refractory chromite to the U.S. steel industry.

In many instances, mineral imports are tantamount to apparent consumption. By far the most important mineral import is crude petroleum for domestic refining; the value of crude imports in 1963 appeared to be a little higher than that of ₱161.5 million in 1962. The origins of the crude were mainly Indonesia, Saudi Arabia, Iraq, and Borneo. Scrap, refined metals, and semimanufactures for processing and consumption in the Philippines represent another leading general category of imports. Japan and the United States were the principal metal suppliers. Some Philippine copper minerals are smelted in bond in Japan and the refined metal is returned to the Philippines for fabrication. The country imports sizable amounts of chemical and fertilizer raw materials from the United States.

TABLE 2.—Exports of selected metals and minerals[1]

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destination, 1962
Chromite:[2]			
Metallurgical	99,547	71,868	All to Japan.
Refractory	531,892	370,423	United States 233,730; United Kingdom 67,523; Italy 33,915; Japan 18,593.
Copper:			
Ore	31,447	25,855	All to Japan.
High-gold concentrate	23,163	35,737	United States 35,737.
Ordinary concentrate	215,880	156,604	All to Japan.
Scrap	2,904	1,733	Do.
Total metal content[3]	52,000	51,000	Japan 43,500; United States 7,500.
Gold:			
Bullion troy ounces	167,068	276,254	All to United States.
Concentrate and matte	21,178	29,984	Do.
Iron ore or equivalent:			
Ore	1,255,073	1,247,981	All to Japan.
Concentrate	54,825	86,921	Do.
Pyrite cinder	7,700	11,400	Do.
Total	1,317,598	1,346,302	Do.
Manganese ore	25,116	8,504	Japan 4,440; United States 4,064.
Mercury 76-pound flasks[4]	1,690	3,444	Japan 3,444.
Molybdenum concentrate	[3] 240	239	United Kingdom 218; Japan 21.
Zinc concentrate	3,100	7,550	All to Japan.

[1] Exports of nonmetallic minerals and fuels were of little consequence.
[2] Company figures for 1962 are much higher: Refractory exports, 424,500, metallurgical exports, 94,180.
[3] Estimate.
[4] Although mercury is final product, figures reported represent estimated metal content of concentrate.

COMMODITY REVIEW

METALS

Chromite.—In 1963, the Consolidated Mines, Inc., Coto open pit the sole Philippine producer of refractory chromite, was exhausting its reserve of good-grade ore but the adjoining Zambales Reservation extension appeared to offer a significant reserve. Although Acoje Mining Co., Inc. does not have a similar monopoly in metallurgical chromite, it was the country's foremost producer by far. The metal-

Digitized by Google

lurgical chromite from Acoje's Zambales underground property was shipped almost entirely to Japan, which purchased slightly less in 1963 than in 1962.

Acoje Mining has diversified activities, including oil drilling. In 1963, it was considering the building of a ferrochrome plant. Nickel-platinum ores analyzing 0.87 percent nickel and 0.086 ounce platinum occur at the Zambales property, and a 200-ton-ore-per-day mill may be built to process this material. This company also has a glass plant and a manganese-copper property elsewhere.

Copper.—Philippine copper producers ranked as follows during the first half of 1963 on the basis of percentage shares of the approximately 30,000 metric tons of mine copper produced by the country as a whole: Atlas Consolidated Mining & Development Corp.—46; Marinduque Mining & Industrial Corp.—23 (Sipalay mine—13 and Bagacay Mine—10); Lepanto Consolidated Mining Co.—21; Philex Mining Corp.—7; and other—3.

Atlas Consolidated, associated with Mitsubishi Metal Mining Co. (Japan), after delineating additional reserves at its Toledo mine on Cebu—the largest copper mine in the Far East—expanded the new Biga Road pit in 1963 and made preparations to work underground in the Lutopan section.

Marinduque Mining, associated with Mitsui Mining & Smelting Co. Ltd. (Japan) discovered an important new open-pit orebody (Cansibit) at its Sipalay copper mine on Negroes with a reserve exceeding 100 million metric tons of 0.8-percent copper ore which also contains byproduct molybdenum. The Sipalay mill was expanded to about 5,500 tons of ore per day in 1963, roughly half the optimum future capacity.

The competitive position of the Bagacay copper-zinc-pyrite open-pit mine on Samar, also belonging to Marinduque Mining, was improved as a result of a long-term contract signed with ESSO Standard Fertilizer & Chemical Co. Inc., to provide the latter's Bataan plant now under construction with 180,000 tons of pyrite (1 percent copper) yearly beginning in mid-1965. A 19.5-kilometer aerial tramway was being constructed in 1963 to transport the pyrite. The sulfur, copper, and eventually iron values of this pyrite, together with the mine copper and zinc now extracted, should place Bagacay on a sound financial footing. The complex ores of Bagacay occurring in Tertiary tuff and with associated barite and gypsum resemble the widespread "black ores" of northern Japan although they contain hardly any lead.

The Amex-Nippon pit, a US$20- to US$30-million project financed by American-Canadian capital in association with Nippon Mining, was being developed during 1963 on Marinduque and is a potentially significant copper producer. The first half of a 8,000-ton-ore-pre-day mill was scheduled to be in operation by mid-1964 to work the presently known reserve of 20 million to 50 million tons of 0.5- to 0.9-percent copper ore, at least half of which is 0.8-percent grade.

Lepanto Consolidated, taking a conservative stand on working a bonanza underground copper-gold mine in Mountain Province, had another highly profitable year in 1963. Philex Mining, with its relatively new Santo Tomas block-caving mine, increased copper output slightly during the year. The ore analyzes about 0.74 percent copper

Digitized by Google

with additional gold values. The company's mill was modified and may be moved to a new site and expanded to 6,000 tons.

In 1963, Marinduque Mining was still seriously considering the construction of an integrated copper smelter. The original plan was to build a Sherritt Gordon process (direct smelting) copper-zinc-fertilizer plant near Iligan on Mindanao. Planning went as far as getting approval of a US$13 million loan from the U.S. Export-Import Bank. Subsequently, plans for the fertilizer plant were dropped because of ESSO Fertilizer's Bataan plant. A new feasibility study for copper, probably on the basis of a conventional process, was being made in mid-1963 by Western Knapp Engineering.

The Phelps Dodge Copper Products Corp., 35 percent owned by Atlas Consolidated, ceased to qualify as a protected new industry and had to contend with high-raw-material-cost problems in 1963; Atlas Consolidated's mine copper, returning from Japan as refined metal, was the raw material used in making rolled copper products.

Gold.—The gold industry was not quite able to hold its own in 1963. Benguet Exploration Inc., the producer normally accounting for nearly half the Philippine gold output, had a 2-month labor strike at its underground operation beginning in early March. This company managed the refractory chrome mine of Consolidated Mines and was branching into other lines of business including copper. Itogan-Suyoc Mines worked lower grade gold ore in 1963 at reduced milled tonnages. Baguio Gold Mining Co. was only able to develop enough new reserves to sustain operations. However, Benguet Exploration's small but very rich underground gold mine near Baguio continued to pay big dividends in 1963. Daily ore output was only 40 to 50 tons, but this ore contained about 1.25 ounces of gold and 8 ounces of silver per ton, 12 percent zinc, 0.8 percent each of copper and lead, and some byproduct cadmium. Recovery of the zinc from newly mined ore and 4 years of accumulated tailings was initiated.

Byproduct gold output from copper producers showed a 15-percent-plus increase in 1963 over that of 1962 and approached 100,000 ounces, or nearly one-fourth of all gold produced by the Philippines. Among the big three, the production of Lepanto declined slightly, that of Atlas nearly doubled, and that of Philex rose by more than one-fourth.

Iron Ore and Steel.—Iron ore for export and steel made from scrap were still unrelated activities in the Philippines in 1963; however, an integrated steel industry was in the process of formation. At Philippine Iron's Larap open-pit mine—the country's largest iron ore producer—construction of a 4,500-ton-per-day concentrate mill with a US$5 million loan from the U.S. Export-Import Bank was well underway in 1963. At the Sibuguey mine of Samar Mining Co. Inc. on Mindanao, the second-ranking iron ore producer, an 11-kilometer aerial tramway was being considered in 1963, possibly in anticipation of providing ore to the proposed steel plant nearby.

The latest and probably most feasible integrated steel project envisages the construction of an electric smelting Linz-Donawitz (LD) converter steel works of 320,000-ton-steel-ingot-yearly capacity at Iligan City, Mindanao, to use domestic iron ore (possibly first converted into sponge iron) and imported and/or local coals. The Jacinto interests (through Iligan Integrated Steel Mills Inc.) already a pro-

Digitized by Google

ducer of steel products and recipient of a US$62.3 million loan from the U.S. Export-Import Bank, is to head up a consortium to manage the operations. Eventual construction of such a plant remained contingent upon hydropower generating capacity yet to be built.

Manganese.—General Base Metals, Inc., affiliated with the management of Acoje Mining, was a leading manganese ore producer and sold manganese to Japan and to domestic ferromanganese and dry battery manufacturers. In 1963, General Base Metals considered building a flotation plant to beneficiate 140 tons of low-grade ore per day in order to gain marketing advantages.

Other Nonferrous Metals.—Mine zinc output in 1963 was about the same as in 1962, with production of Bagacay Mine (see under Copper) a little lower and Benguet Exploration (see under Gold) somewhat higher. Bagacay had difficulty in cleanly separating copper and zinc. Mine lead production continued to be nominal, and lead battery plants had an uneventful year in 1963. Molybdenum output showed no great change despite expanded milling capacity at the Sipalay copper operation where molybdenum concentrate is produced.

Elsewhere in the nonferrous field, mercury production by the sole producer Palawan Quicksilver Mines Inc. was down slightly in 1963, because of price decline, grade problems, and increased cost brought about by the "decontrol" of the peso exchange rate.

NONMETALS

There were few new developments in the nonmetallic field during 1963. Demand for cement was such that efficient plant capacity was well utilized; high-cost, coal-fired kilns found it difficult to meet competition. The possibility of using lightweight aggregates, including perlite, was explored.

Plans to recover and use more pyrite as a source of sulfur was a significant event in 1963, because significant quantities of pyrite are associated with copper. Atlas Consolidated discards or stockpiles the surplus pyrite from copper ore when it is not sold or consumed at the subsidiary fertilizer plant. In addition, the company has an undeveloped pyrite deposit at Toledo. The Bagacay pyrite tie-up with ESSO has been mentioned.

MINERAL FUELS

In 1963 the large and rising demand for liquid fuels continued to be met by imports. Extensive exploration for oil has taken place in the hope of overcoming this striking and costly deficiency, with no significant results as yet. However, self-sufficiency in oil refining capacity was achieved in the Philippines during 1963 with the completion of the fourth plant. Some natural gas finds may prove economically feasible for development. ESSO's interest in byproduct fertilizer is significant.

The coal market showed no improvement in 1963. Another survey of the Malangas coalfield on Mindanao was being considered, and this might prove useful in connection with the proposed integrated steel plant.

The Mineral Industry of Taiwan

By J. M. West[1]

TAIWAN'S mine production index advanced 5.2 percent in 1963 despite a devastating September typhoon. Earlier in the year, some mineral processing plants, such as aluminum, carbide, and fertilizers, had temporarily shut down because dry weather had caused a shortage of hydroelectric power. Mine output, largely coal, provided 2.5 to 3 percent of the 1963 gross national product of approximately US$1.5 billion. By including the added values derived from smelting and processing, however, the total mineral share of the GNP was closer to 10 percent. Although of little consequence by world standards, Taiwan produced about a third of the cement and coal plus a fair share of the steel in the free world Far East, excluding Japan. In the past decade, coal output had doubled and cement quadrupled. Except for coal, limestone, and natural gas, the Island's mineral resources had little to offer the economy.

The steel industry, based largely on electric smelting of scrap, was in a precarious condition due to the small and marginal nature of operations. Taiwan was able to compete with Japan for cement exports, because of low-priced coal (but high in mining cost) and U.S. AID marketing connections that counterbalanced high freight rates. A sizable oil refinery processing imported crude was in existence, and the feasibility of establishing a large integrated iron and steel complex based upon local coal and imported iron ore was under study.

The most significant mineral development in 1963 concerned natural gas. Deep wells in several fields near Miaoli in northwestern Taiwan struck commercial reserves of gas large enough for supporting industrial plants and possibly also for piping to various urban centers for household use. As a result of these discoveries, a gasoline plant at Touwu and two fertilizer plants (one urea-ammonia and the other ammonium sulfate) at Miaoli were being constructed. To meet the new demand for sulfur in making fertilizers, plans were made to increase domestic production of pyrite and mixed pyrite-sulfur ores.

The Chinkuashih gold-copper mine of the Taiwan Metal Mining Corp. was also in the news in 1963; exploitation began on the rich gold ore shoots discovered and a separate mill was being constructed. A government-run pilot coal cleaning and research facility neared completion at Chin-mei. Sinking of an incline at the Chien-chi coal mine was started to mine offshore coal seams in the Keelung area. At Kaohsiung, construction started on a lubricating oil plant, aluminum plant expansion was completed to 20,000 tons per year, and Universal Cement Corp. began operation of its new 200,000-ton cement plant. Detailed information on Taiwan's mineral deposits, resources, and production was published.[2]

GOVERNMENT POLICIES AND PROGRAMS

Taiwan, with a balanced agricultural-industrial economy supporting a 12 million population and a large standing army, has achieved a fairly high level of economic development by Far Eastern standards, despite restrictive measures on the part of the government. The U.S. AID program, mainly in the military and agricultural fields was due to be phased out, had contributed significantly to the island's progress. The Chinese Government, while stressing the development of the relatively poor mineral resources, placed more emphasis on building up mineral processing, industrial, and power facilities to use imported as well as indigenous minerals.

Although private investment was encouraged, most of the major mineral enterprises were still in government hands as of 1963, with the coal and cement industries as the only major exceptions. The coal industry, however, was regulated according to requirements and price offerings of government-controlled industries which consumed most of the product. Some new fertilizer and steel plants were privately owned. On the other hand, the government ran the oil refining, natural gas, salt, aluminum manufacture, and gold-copper industries as well as most of the important plants in fertilizers and power. Government policy in 1963 was clearly to rely more heavily on private enterprise for industrial development in the future.

The third 4-year plan ending in 1964 had called for total expenditures of US$34 million on mineral resource development; final targets for coal, gold, and silver were already surpassed by 1963. Efforts to relax import controls resulted in abolishment in September 1963 of the foreign exchange certificate system whereby traders had been required to deposit the full value of goods when applying for import licenses. Importation of mineral and industrial equipment was thus made easier.

The Mining Research and Service Organization (MRSO), under the Ministry of Economic Affairs, performed technical aid and planning functions with the assistance of the U.S. AID Mission to Taiwan. Initial work was primarily in coal mining and economic geology. MRSO started in March 1963 to publish a monthly periodical in Chinese entitled "Mining Technical Digest."

With a thriving economy, relatively low corporate taxes, and few restrictions regarding convertibility of profits, Taiwan had one of the most favorable investment climates in the Far East. Natural gas and its potential for wider use attracted the interest of U.S. investors during the year. Japanese investors were looking at possibilities to participate in gas distribution, steel, and chemical industries but were restrained, at least temporarily, by a government move in November stopping any further approvals of Japanese investments. The action was retaliatory after reported Japanese trade talks with mainland China.

PRODUCTION

Cement and coal, Taiwan's main mineral products, were valued at about US$40 million each in 1963, with iron and steel products worth an estimated US$20 to 25 million. Fertilizer manufacture, mainly nitrogen-based but including large quantities of ammonium sulfate utilizing domestic pyrite and imported sulfur, was about even with steel at roughly US$25 million. Coal provided part of the basic ingredients plus electric power for making fertilizers. Salt, gold, copper, and sulfur values ranged downward from US$1.8 million to US$0.7 million. Other minerals included limestone, clays, dolomite, and talc. Petroleum refining was dependent on crude imports and supplied most domestic needs for refined products; crude oil production was insignificant. Natural gas output and sales neared US$1 million, and prospects were good for sizable expansion based on new discoveries. Cement and coal in 1963 were up 21 and 6 percent, respectively, over 1962. Steel and natural gas jumped about one-third. Gypsum used in cement was produced as a byproduct of salt evaporation and was supplemented by imports. Aluminum output, although 9 percent ahead of 1962, was considerably less than capacity owing to power shortage.

TRADE

Mineral imports in 1963 were valued at an estimated US$60 to $65 million, about twice that of mineral exports. Crude petroleum and iron and steel products, about the same level as in 1962, led the imports comprising about two-thirds of the total value. Fertilizers and sulfur also were impressive. Nearly one-fifth of the total 1963 mineral import value was in chemical fertilizers. Tonnages of fertilizers, while large in 1963, were off nearly 30 percent from those in 1962. Sulfur valued at US$1.3 million was about three times the 1962 value and quantity.

The United States and Japan were principal trading partners of Taiwan. Crude oil was supplied from the Middle East, metals chiefly from Japan and Australia, and fertilizers from Japan, except for phosphatic and potassic types imported from the United States. The main source of iron ore was Malaya; of bauxite, Sarawak; of sulfur, Canada; and of steel scrap, United States. Part of Taiwan's imports were provided through U.S. AID.

Cement and iron and steel products were the leading exports, with cement worth about US$14 million in 1963. Tonnage of iron and steel exports was higher than in 1962 and came close to half of that imported. The majority of cement and iron and steel appeared to be going to South Viet-Nam and Hong Kong in 1963 as in 1962. Coal, mainly coking grade, was exported to Japan and South Korea; salt, copper ores, and copper products to Japan; and gasoline and fuel oil to the Philippines.

TABLE 2.—Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	Principal destinations, 1962
Metals:

COMMODITY REVIEW

METALS

Aluminum.—Taiwan had the only aluminum reduction plant among the smaller countries of the Far East. Taiwan Aluminum Corp., the Island's sole aluminum producer, recorded a 9-percent production increase from 1962. About half of the production was in sheets and strips and the rest extrusions, foils, and other shapes. The company's new Pechiney-design potline at Kaohsiung was completed in June 1963 raising ingot capacity to 20,000 metric tons per year. Bauxite,

Digitized by Google

imported mainly from Sarawak, was processed in the plant's Bayer alumina section. Also some 2,500 tons of bauxite went to firebrick and related industries. An estimated 60,000 tons of bauxite was imported in 1963 with 90,000 tons expected in 1964. Aluminum exports, over half in the form of ingots, totaled about 4,100 tons in 1962 and were probably higher in 1963.

Copper, Gold, and Silver.—Chinkuashih, together with the nearby Chiufen and Wutankeng mines in northern Taiwan, supplied nearly all the copper, gold, and silver production. Taiwan Metal Mining Corp. extracted ores at Chinkuashih averaging less than 0.8 percent copper, mainly in the form of enargite, with abundant pyrite recovered as a byproduct for its sufur. Output of copper in 1963 fell about one-third from that in 1962 owing to Typhoon Gloria which caused an estimated US$250,000 damage to mine facilities. The value of gold and silver produced in 1963 slightly exceeded that of copper.

At Chinkuashih 10 or so pipelike ore bodies were mined and cement copper was recovered from mine waters by collection on iron scrap. Gold was more important than copper in some of the ores. Cyanidation was used to treat the gold ores, flotation-cyanidation for gold-copper ore, and flotation for copper ore. Concentrates and most of the cement copper were shipped to Japan for smelting. Bonanza gold ore shoots discovered in October 1962 between the second and main sublevels of Adit No. 4 were being mined, and during the 6 months following discovery 200 tons was extracted averaging 31.8 ounces per ton in gold. Preliminary estimates placed the reserve at 800,000 tons of ore but grade was very erratic. A 24 ton-per-day mill was due in operation by mid-1963 to treat the rich ore. Copper mining was largely confined to Adit No. 7, while efforts were underway to pump out the No. 8 main level extending 420 feet below sea level, with mining to start there in 1964. Sand filling, begun in 1962, helped support stopes and effectively reduced mining costs. Scrap and some cement copper were processed in a small smelter-electrolytic refinery at Chinkuashih but the plant was considered uneconomical to operate on mine production.

Iron and Steel.—Production, which had been expanded tenfold from a decade ago, was not very large. Output of ingots and castings was 75,000 tons greater in 1963 than in 1962. Roughly a dozen small capacity plants produced ingots and castings; about 30 others produced ingots and rolled products. The most important plant, also the Island's largest private enterprise, was the 90,000 ton per year Tang Eng Ironworks at Kaohsiung.

Pig iron was produced by Taiwan Iron Manufacturing Co. at Sitze, using a 50-ton-per-day blast furnace and local ores. Taiwan had no important iron ore deposits; the only production came from magnetite beach placers on the northern coast, mined by retired servicemen, and a small quantity of limonite bog iron that supplied local demand. Iron ore was also imported from Malaya, averaging about 40,000 tons per year in 1961–63. Scrap mainly from the United States and Hong Kong supplied a third to a half of the iron requirements.

Steel product imports were estimated at 150,000 tons in 1963, about the same as in 1962, but exports were higher at about 70,000 tons. Exports in 1962 were valued at US$12 million and went mostly to South Viet-Nam and Hong Kong. Ferroalloy exports showed a significant

Digitized by Google

rise from 590 tons in 1962 to an estimated 4,300 tons in 1963, nearly half ferromanganese and the rest ferrosilicon. The government was urged to remove an existing ban on bringing old ships to Taiwan for scrapping. A project was under study by Kaiser Engineering Co. (United States) to build an integrated iron and steel mill costing on the order of US$50 million. Such a plant was strongly encouraged by the government, but market justification appeared to be lacking.

NONMETALS

Asbestos.—Commercial asbestos production came from one deposit, Fengtien, in the Hualien area of eastern Taiwan. The asbestos was mostly brittle and weak, comprised of actinolite and tremolite varieties. Mining was intermittent, 40 to 50 tons of asbestos powder being produced per month. Serpentine also had been mined at Fengtien for flux in making phosphate fertilizers at Taiwan Fertilizer Co.'s Lotung plant but production was stopped in 1960 when it was found farmers were reluctant to use such compounds.

Cement.—Fears of overproduction were dispelled by brisk export sales mainly to South Viet-Nam and Hong Kong. Domestic consumption in 1963 was estimated 1.3 to 1.4 million metric tons and per capita was second only to Japan among Asiatic countries. Production, 21 percent higher than in 1962, surpassed the 4-year plan's 1964 target of 2,160,000 tons as facilities were operated at maximum levels. Ranked about fifth in world cement exports, Taiwan shipped abroad an estimated 900,000 tons of cement including 70,000 tons of white cement in 1963. Exports were nearly double those of 1962. The rise in white cement exports from a few thousand tons in 1962 was significant in view of competition from Japan.

Taiwan Cement Corp., a former government enterprise transferred to private ownership, was the largest producer, with one plant each at Kaohsiung, Suao, and Chutung, plus a new plant completed in 1962 at Hualien. With startup of a new kiln at Kaohsiung in November 1962 the company's annual capacity rose to 1.2 million tons, over half of the Island's total. Company profits were reported at US$3.93 million in 1962. The same company announced investment in a new Hong Kong cement plant under construction in 1963 on Tsing Yi Island and received approval to export 20,000 tons of cement to Hong Kong as part payment. Plans were to utilize Taiwan clinker.

Taiwan manufacturers prepared to supply cement clinker to new finishing plants in South Korea and South Viet-Nam. Producers were awarded contracts in 1963 to supply 250,000 tons of finished cement to the Philippines and 100,000 tons of clinker to South Korea. The new US$6.3 million 200,000 ton plant of Universal Cement Corp. at Kaohsiung began operation in May 1963. A major portion of its production was marked for export.

As new foreign plants in underdeveloped countries reached production stage, Taiwan's export markets were expected to fall. Hence, a three point program was drawn up by the Ministry of Economic Affairs' Planning and Coordination Group advocating temporary halt in cement plant expansion and construction, assignment of export controls and promotion to Taiwan Cement Corp., and more effort to

Digitized by Google

reduce cost and increase sales. Objectors viewed the plan as contrary to government policy to encourage free competition also complaining that lack of surplus capacity would result in shortages during high demand periods of the year.

Dolomite.—Most of Taiwan's 1963 production of dolomite came from the Hualien area on the east coast. Small quantities were dead-burned by Taiwan Metal Mining Corp. in a vertical kiln pilot plant, and the product was used successfully as furnace bottom by Keelung Iron & Steelworks. Taiwan Mineral Resources & Industry Co., Ltd. completed a US$250,000 plant at Hualien to calcine dolomite making plaster and magnesian fertilizer partly for export markets. The plant was supplied with a small tonnage of the mineral imported from Japan in 1963. Detrital dolomite was obtained from stream sediments renewed by annual floods in the Hualien area although extensive but poorly accessible bedded deposits existed nearby at Chingchang Shan and Chingchangchi.[3] The only dolomite quarry in Taiwan was along the Suao-Hualien Highway where three operators produced about 2,000 tons per month, half going to iron smelters, chiefly the Tang-Eng Ironworks in Kaohsiung.

Graphite.—The main graphite producer was the Paileng deposit at Taichung-hsien. Used chiefly in crude paints, roofing compounds, and pencil leads, the graphite was associated with altered and recrystallized coal and was poor quality amorphous, perhaps better described as graphitic slate.

Marble.—At Hualien, Vocational Assistance Commission for Retired Servicemen operated a marble processing plant and was planning to build a second plant costing about US$500,000 during 1964 to meet increasing demands. Yu Hwa Industrial & Mining Marble Corp. also operated a marble plant and quarry at Hualien.

Salt.—Record output in 1963, made possible by favorable weather, exceeded the production target and was 5 percent higher than in 1962. The important salt fields were along the southwest coast. Nearly one-half of the production, about 283,000 tons, was exported mainly to Japan providing US$1.5 million in foreign exchange.

Crude salt was processed by the Taiwan Saltworks and Taiwan Alkali Co. Taiwan Salt also treated residual bitterns in plants at Putai and Anping extracting byproducts such as gypsum for cement, sodium sulfate for glass and paper making, and magnesium compounds for paper, refractory, and fertilizer industries. About 50,000 tons of washed salt and 1,200 tons of refined salt per year were produced mainly at Anping. Industrial salt consumption was nearly six times higher than a decade ago. Salt went into making caustic soda, chlorine, and soda ash. Estimated 1963 production of caustic soda totaled 44,400 tons and soda ash 12,400 tons. Government-owned Taiwan Alkali Co. operated electrolytic caustic-chlorine plants at Kaohsiung and Anshin, producing three-fourths of the caustic output. Eighteen or so private manufacturers also produced alkalis.

Sulfur, Pyrites, and Fertilizer.—Native sulfur, pyrites, and petroleum refinery off-gases provided about two-thirds of the Island's sulfur re-

[3] Matsuo, Tadayoshi and Shigeo Takeuchi. Report on the Development and Utilization of Dolomite in Taiwan (in Chinese). Mining Research and Service Organization, Ministry of Economic Affairs, Taiwan, December 1963, 28 pp.

Digitized by Google

quirements in 1962 but less than half in 1963 as demand went up; sulfur imports largely from Canada supplied the balance. Apparent consumption of sulfur doubled from about 35,000 tons in 1962 to 70,000 tons in 1963; meantime, imports nearly tripled in 1963 to an estimated 45,000 tons while production rose only a few thousand tons. Most of the sulfur was used in making paper and fertilizers. Ammonium sulfate fertilizers were highly popular with Taiwan farmers, and efforts were being made to expand production and thus cut import expense. Estimates of demand in 1964 were placed at 55,500 tons for sulfur and 145,700 tons for pyrites, both considerably higher than projected outputs. The government called on sulfur and pyrite miners to increase production and proposed guaranteed markets. In late 1963 the Central Trust announced invitations to bid on supply of 55,000 tons of sulfur.

Natural sulfur was produced from solfatara deposits of the Tatun Volcanic Group in northern Taiwan at low yield 50 percent extraction rates. Major producers were Tekke Mining Co., San Chin Mining Co., and San Li Mining Co. Pyrites, however, were a more important source of sulfur, the output totaling 46,760 tons (about one-third sulfur) in 1963. Most of this came from flotation plants at the Chinkuashih and Chiufen mines where the mineral comprised about 8 percent of gold-silver tailings. Several small plants (10 ore-tons per day) for floating "black pyrites" that occur with sulfur in the Tatun deposits, were operated in the Chihsing-Shan region. Taiwan Metal Mining Corp. ran tests during 1962 with a pilot flotation mill at the Chihsing-Shan mine to determine best treatment for such ores.[4] The company considered building a plant (200 ore-ton-per-day) at either Payen or Chiku for precessing the mixed ores of nearby deposits. Ore reserves in the surrounding area were estimated to total 2.6 million tons averaging about 13 percent native sulfur and 772,000 tons of sulfur in pyritic ores in which the pyrite contained 15 percent or more sulfur.

Production of fertilizers in thousand metric tons were as follows:

Fertilizer	1962	1963	Fertilizer	1962	1963
Calcium cyanamide	79	64	Urea	75	76
Nitrochalk	58	55	Calcium superphosphate	144	172
Ammonium sulfate	68	108			

Phosphate rock for making superphosphate was imported from the United States and Morocco (estimated 30,000 and 12,000 tons, respectively, in 1962). Fertilizer imports, largely from Japan, fell 29 percent to 258,294 tons in 1963, with ammonium sulfate, the most important, dropping to only about half of that imported in 1962. Imports were expected to drop still further in 1964 with completion in December 1963 of a large natural-gas based urea-ammonia plant built by Mobil China Allied Chemical Industries, Ltd. at Miaoli. A 120,000-ton-per-year ammonium sulfate plant using ammonia from the Mobil

Digitized by Google

plant and due for completion by Taiwan Fertilizer Co. (TFC) also at Miaoli in early 1964 was being equipped with a Japanese-made 300-ton-per-day sulfuric acid pyrite roaster. Central government-controlled TFC, with seven of the country's eight fertilizer plants, produced 466,168 tons of chemical fertilizers in 1963 and aimed at 497,000 tons in 1964. The eighth plant, run by Provincial Government-owned Kaohsiung Ammonium Sulphate Corp., was being expanded. TFC was laying plans to build a US$1 million phosphoric acid plant, part of the production to go into superphosphate and mixed fertilizers.

MINERAL FUELS

Coal.—Coal, exceeded only by cement in mineral production value, provided about four-fifths of Taiwan's mine output in 1963. Production was 6 percent higher than in 1962, this, despite extensive mine damage by the typhoon that hit in September. About one-fifth of the production was coking grade. Operating coal mines at the beginning of 1963 totaled 315, of which about 175 produced more than 1,000 tons per month. Demand was rising, especially for thermal power use, but coal seams were mostly thin and mines could not readily be expanded; hence, the necessity of opening new mines to push production higher.

The industry was burdened with high mining costs, hazardous operations, health problems, and low prices set by the major consuming government enterprises. The death rate from coal mine accidents was 30 to 50 persons per million tons of coal, almost 100 times higher than most other countries. There were 88 fatalities in the first half of 1963 mostly from gas explosions that resulted from failure to provide adequate ventilation. Hookworm disease seriously reduced mine workers efficiency. Coal producers requested increases in basic coal prices but were turned down in the interest of price stability; however, some relief was given by increased credit. Severe competition had depressed coal prices 4 percent in 1963. To ease the burden of large inventories Taiwan Power Co., the principal consumer, agreed to take advance 1964 deliveries of 200,000 tons of coal. The company's requirements for 1965 were estimated at 1.75 million tons rising to 2.58 million tons by 1970.

Main markets for coal exports were Japan and South Korea. Shipments of 90,735 tons in 1963 were almost two-thirds less than in 1961. Losses on shipments to Korea doubled as competition with Australian and Japanese suppliers dropped Korean coal prices from US$11 in 1962 to US$9.30 in mid-1963.

Taiwan's coal requirements for 1967 were estimated at 6 million tons; it appeared there would be a deficiency from 1964 on, so no surplus would be available for export. Electric generating capacity was growing. The third unit of the Kaohsiung thermal plant was due in service by the end of 1963, and a 200,000 kilowatt thermal plant was scheduled for operation at Shen Ao in 1965–66. Also, the government was planning two 300,000 kilowatt thermal units to be completed in 1968–69. Taiwan Railway Administration, the largest consumer of lump coal sizes, was replacing steam with diesel locomotives, so some excess lump was predicted.

Digitized by Google

To boost coal production the government was developing six new mines to open in 1964–65 and planned opening of seven others as demand indicated. Few mines had coal washing facilities, and to improve mining and coal preparation methods, Taiwan's Mining Research and Service Organization and Provincial Coal Adjustment Commission was establishing a pilot coal cleaning plant and research laboratory at Chin Mei. Equipment installation was nearly complete at yearend. One project was to reduce sulfur content of coal below the 2.5 percent maximum set by Taiwan Power Co. Mine operators were anxious to get mechanical equipment suitable for complex local mining conditions. In general the new mines had seams only 12 to 28 inches thick. Arrangements were being made to obtain on trial from West Germany a Westfalia-Lunen Co. Ram Plough for use in the Yungting mine of Taiyang Mining Co. Yielding steel props were purchased for trial use in long-face mining at the Chien Chi mine. Prestressed concrete roof supports were used experimentally in several mines.

Offshore coal mining was of growing importance. Seven coal belts have been proven to extend off the northern shores of Taiwan and drilling of three holes was proposed to test extension underwater of two other belts. Three suboceanic mines were planned: Chien Chi, Taipei-hsien; Masu, northwest of Keelung; and Yungchiu, north of the Chinkuashih mine. Work began and Chien Chi in February 1963 on a 2-year project to sink a 3,900-foot incline dipping 18 degrees to reach a seam containing an estimated 16 million tons of coal 1,085 feet below sea level.

Coking coal went chiefly to the Pioneer Chemical Corp. byproduct coke oven plant at Nankong, Taipei-hsien, in operation since October 1961. More wasteful beehive ovens were being phased out over several years. Pioneer operated at about two-thirds of its 150,000 tons coke and 1.6 billion cubic feet of gas annual capacity, producing besides coke, ammonium sulfate, coal tar and pitch, light oils, and other products. Some of the pitch was exported to South Korea for use in making briquets.

Natural Gas.—The 1,630 million cubic feet of natural gas used in 1963 was nearly one-third greater than in 1962 resulting from new supplies developed at the Chinshui field, northwestern Taiwan. Gas finds came on the heels of growing criticism of unsuccessful explorations: China Petroleum Corp. had completed 11 producing gas wells at Chinshui by early 1963. In November its Chinshui Well No. 53 reached a producing horizon that provided an additional 8 million cubic feet daily potential output and brought Taiwan's overall capacity up to 42 million cubic feet of gas daily. The most productive zone was about 8,000 feet in depth. Deep drilling at 11,000 to 14,000 feet also disclosed commercial gas in the old Chuhuangkeng oilfield and the Tiehchenshan anticline; explorations were planned of favorable oil and gas structures at Tatushan and Paishatun.

Encouraging news brought a flurry of interest in gas distribution and utilization.[5] China Petroleum hired an American engineering consultant firm to conduct a survey for a natural gas pipeline from Miaoli

[5] Chang, Stanley S. L., and David K. Y. Chen. Substantial Gas Reserves Reward Taiwan Exploration Campaign. World Petroleum (London). April 1963, pp. 46–49.

Digitized by Google

to Kaohsiung in the south and Keelung in the north. The US$22.5 million fertilizer plant of Mobil China Allied Chemical Industries, Ltd. utilizing gas from the Chinshui field was completed at Miaoli in December 1963. This was a joint venture of China Petroleum Corp., Socony Mobile Oil Co., Inc., and Allied Chemical Corp. and had capacity of 100,000 and 45,000 tons per year of urea and ammonia respectively. A gasoline absorption plant at Touwu due for completion in 1963 was to supply the fertilizer plant with gas, processing 35 million cubic feet daily, and extracting about 100,000 barrels of gasoline per year. Construction was expected to start in late 1964 on a natural gas pipeline from Chinshui to Hsinchu, and gas distribution facilities at Hsinchu were being planned.

Petroleum.—About 1.49 million metric tons of crude and diesel fuel oil was imported for refining and use in 1963. Taiwan had a small production of oil, in 1963, mostly from the Chinshui field, and this was processed in a small refinery with a few hundred barrels per day capacity at Miaoli.

Petroleum product consumption, excluding the military, was estimated at 4.2 million barrels in 1963 compared with 3.7 million barrels in 1962. For bunkering in 1963, 500,000 barrels of fuel and diesel oils went to commercial ships while civilian aircraft consumed 44,000 barrels of aviation gas and 72,000 barrels of turbine fuel. With exception of lubricants all domestic civilian requirements were met by the 35,000 barrel-per-day Kaohsiung refinery of China Petroleum Corp. (CPC) operating on Middle East crudes. About two-thirds of the lube oil needed was imported and the balance produced in a CPC blending plant. Construction was started in September 1963 on a US$7.7 million 1,500 barrel-per-day lubricant plant being built by Gulf Oil Co. in partnership with CPC. The plant, to use partly reduced crude from CPC, was due for operation in 1965, with half or more of the output intended for export markets.

An American oil exploration group negotiated with the government but apparently was short of an agreement for oil and gas exploration rights in the southern half of Taiwan.

The Mineral Industry of Thailand

By J. M. West [1]

THE mineral sector of the Thai economy was far less important than agriculture, the principal source of livelihood for the country's 30 million people. However, the mineral industry showed an interesting potential. Minerals, largely tin, contributed only 1 to 1.5 percent of the approximate US$3.1 billion gross national product (GNP) but accounted for 8 percent of the value of the total exports. The GNP was estimated to be 6 percent higher than in 1962. Tin was an important source of foreign exchange, as Thailand was the world's fifth-largest tin producer, with 7 to 8 percent of world production. Most of the tin came from the peninsula leading south into Malaya. Besides tin, Thailand produced 1 to 2 percent of the world's antimony, about 1 percent of the fluorspar, and slightly less than 0.5 percent of the tungsten. The year brought sharp rises in antimony and fluorspar production, appearing to mark Thai entry as a world producer of some importance for these minerals.

Among the few significant developments during 1963 were two oil refineries nearing completion: one a 36,000-barrel-per-day plant at Sriracha to supply commercial distributors and to operate under Shell International Oil Co. management; the other a 5,000-barrel-per-day Government-built plant near Bangkok. The lignite-burning Krabi powerplant, approaching completion in southern Thailand, was to be supplied from newly developed mines. Oil exploration concessions in the north were granted to at least two companies. Five or more companies held concessions and searched for iron ore. The following were planned or considered: a tin smelter, integrated iron and steel making, a nitrogenous fertilizer plant, a cement plant for southern Thailand, and at Bangkok a steel rolling mill, a pipe plant, and electric furnace installations.

GOVERNMENT POLICIES AND PROGRAMS

In recent years, the Thai Government embarked on the policy of encouraging foreign investment in local mineral exploitation. For example, potential investors were offered inducements under the Industrial Investment Promotion Act passed in 1962 that granted special benefits for priority industries.[2] In 1963 this fast-developing country with a fairly promising mineral resource base also has political stability, a sound monetary structure, and favorable atmosphere for con-

Digitized by Google

tinuing economic growth. The 1961–66, 6-year plan sought to raise GNP by 4 to 5 percent annually, but the figure was subsequently revised upward to the 6 percent rate achieved in 1963. Greater emphasis was to be placed on rural development in the revised plan. A program was in effect to boost tin output at least 5 percent a year. This was possible since the Thai export quota under the International Tin Agreement was raised July 1, 1963.

Thailand maintained a small but active Department of Mines, which handled leases and concessions, regulated tin production and sales, supervised the purchase, transport, and sales of certain minerals, and conducted geological, mining, and metallurgical tests and studies. An Agency for International Development-backed program, started in 1960 to assist the Department in training personnel and investigating sedimentary rocks in the northeast provinces, was dropped in 1963.

In a far-reaching reorganization, the Thai Cabinet decided in April 1963 to consolidate 13 departments and 3 state enterprises under a Ministry of National Development. With the changes, the Department of Mines and Ministry of Industry were combined to form the Department of Land Resources. Several separate electricity authorities were merged into one National Electricity Authority, giving promise of simplified power-rate structure.

The Government was building power projects and linking electrical distribution lines. The Yan Hee 560,000-kilowatt hydroelectric project with its Bhumibol Dam, seventh largest in the world, neared the initial operating stage due in 1964. A 40,000-kilowatt thermal powerplant was being built in conjunction with the Krabi lignite mine project in southern Thailand to serve an important tin mining area. Bids were invited in late 1963 to build the 25,000-kilowatt Nam Pong hydroelectric project in Khon Kaen Province.

Political unrest in neighboring Laos and the break in diplomatic relations with Cambodia limited geological studies in eastern Thailand, and insurgent activities along the Burmese border also held back mineral development in western Thailand.

PRODUCTION

Tin accounted for about 60 percent of the 1963 mineral output by value, cement about 30 percent, salt about 3 percent, and lignite, fluorspar, petroleum, antimony, manganese, lead, tungsten, and iron ore less than 1 percent each in about that order. Marl and gypsum were produced for local use mainly in cement. Lignite, poor in quality, was used mostly for generating electric power locally at Mae Moh. About half of the salt (produced from sea water) and nearly half of the manganese ore mined found domestic markets. Tin production showed a significant 6-percent increase in 1963. Antimony output, including ores and some metal, rose sharply because of activity at one mine. Again as a result of expansion of one mine, fluorspar production jumped to nearly three times that of 1962.

TRADE

Minerals comprised about 8 percent of Thailand's total exports, ranking fourth after rice, rubber, and corn. Mineral exports were valued at US$37.5 million, 90 percent accounted for by tin. Cement and salt together brought in US$3 million, with the balance of less than US$1 million derived from fluorspar, antimony, manganese, tungsten, lead, and iron ores. Two-thirds of the tin went to Malaya. Japan was the main buyer of other ores, except lead which went mainly to West Europe and managanese to Hong Kong. South Viet-Nam received most of the cement.

Fluorspar	[1] 6,962	14,970	Japan 5,862; Taiwan 1,100.
Salt, sea----thousand tons	135	102	Japan 39; Malaya 33; Singapore 23; Hong Kong 19.

[1] Listed with feldspar, leucite, nephelite, and nepheline syenite but believed to be all fluorspar.

Digitized by Google

Petroleum imports valued at an estimated US$55 to US$60 million came mainly from Indonesia and Iran. Imports of steel products based on 10-month 1963 figures appeared to be about 50 percent greater than 1962 imports and were estimated at 410,000 tons for the year. Most of the steel was supplied by Japan. Some white and other special types of cement were imported. Because of agriculture's leading role, fertilizers formed an expanding part of Thai trade. In 1963, about 100,000 tons of fertilizers were imported, half again higher than in 1962. Makeup of the 1962 imports was ammonium sulfate, 43 percent; ammonium phosphate, 25 percent; mixed, 16 percent; and other, 16 percent. Value was about US$4 million, with Japan, West Germany, and the Netherlands being the main suppliers.

COMMODITY REVIEW

METALS

Aluminum.—Aluminum consumption, about 5,000 tons in 1962 and 1963, was supplied from imports. Kaiser Aluminum & Chemical Corp. took a 35-percent interest in Thai Metal Works Co., Ltd., with a 2,500-ton-per-year aluminum sheet rolling plant in Bangkok, in contemplation of a wider range of sheet products. Aluminum Co. of Canada, Ltd., planned a sheet (2,500 tons) and cable (1,500 tons) plant.

Antimony.—Antimony suddenly rose to prominence, contributing about US$400,000 to the Thai economy. Production jumped owing to greatly increased output at the Bansong mine of Siamerian Mining Enterprise Co., Ltd., and the 1964 production was projected at about 1,200 tons. The greatest part of 1963 output was exported to Japan. Handpicked ores and concentrates grading plus 45 percent antimony comprised about three-fourths of the output. Two 1-ton-per-day volatilizing furnaces at Bansong produced about 100 tons of antimony metal; two more similar-size furnaces were under construction. Mining Products Co., Ltd. (Bangkok), American-owned, signed a contract in early 1963 to manage operations.

Iron Ore.—Thailand's iron ore production, never large, dropped in 1963 because of depletion after less than 2 years' operation of the Eastern Mining Development Co. mines on Kao Samui Island off Surajthani, southern Thailand. The company produced 37,612 tons of ore in 1962 and 3,607 tons in 1963 before closing the mines in March. Operations moved in June to another deposit in Nakorn Sawan Province. Siam Cement Co. with a 20-year-old mine in Lopburi Province produced 12,134 tons of iron ore in 1963. Ore all went to the company's Tha Luang iron smelter-cement plant facility.

The Government continued to strongly encourage exploration for large enough iron deposits to supply a medium-tonnage, integrated iron and steel plant. Two firms acquired concessions to explore and mine iron ore; Thai Pin Petch Co., Ltd., in Trang Province, and Stella (Thailand) Co., Ltd., in Amphur Phayuhakiri, Nakorn Sawan Province. The Prime Minister's office in mid-1963 announced iron deposits containing an estimated 10 million tons of ore had been discovered in the northeastern Province of Loei. Two leading Japanese steel companies reportedly signed agreements to purchase in 3 years 400,000 tons of iron ore on a guaranteed-59-percent-iron dry basis from the Thesala mines in southern Thailand. Thailand Steel Co., Ltd., a Thai-Japanese combine, conducted a survey for iron deposits in Nakhon Srithamarat, southern Thailand, under a 1-year concession granted in August 1962.

Iron and Steel.—Except for a few thousand tons of pig iron produced annually by Siam Cement Co.'s small charcoal-fired blast furnace at Tha Lusang and minor scrap smelting, Thailand relied on imports for its iron and steel requirements. Apparent consumption in 1963 was estimated at about 420,000 tons, nearly half again higher than in 1962. Japan supplied about two-thirds of the tonnage consumed. Main imports in 1962 were sheets and plates 99,779 tons, concrete

Digitized by Google

reinforcing rounds 77,456 tons, and tubes and pipes 28,539 tons. Included was 14,621 tons of tinned sheet and plates, 84 percent from the United States.

Forty to fifty foundries operated in the Bangkok area. The Japanese, having completed three sheet-galvanizing plants, planned jointly with a Thai firm to build at Bangkok a 70,000-ton-per-year reversing sheet mill to supply the plants. Mill startup was scheduled for early 1965. Japanese Mitsui Bussan and Mitsubishi Shoji planned electric furnace installations at Bangkok. Monthly production of 7,000 tons of bars and wire rods was expected at the Mitsubishi plant. Castle & Cooke, a Hawaiian-based company, together with Chue Chin Hua, maker of Thai aluminumware, acquired machinery for a US$1 million 15,000-ton, welded-steel-pipe plant, also at Bangkok.

The Thai Government intensified efforts to establish an integrated domestic iron and steel plant calling attention to the discovery of iron ore deposits in the Loei area. Officials of Koppers International, C.A. (United States) and Krupp Co. (West Germany) conferred with the Government over technical planning assistance and financing of a feasibility survey.

Lead-Zinc.—The Nong Phai (Nong Bhai) mine in Kanchanaburi Province continued to provide the bulk of the country's lead-zinc, totaling 2,260 tons of lead-in-ore and probably half as much zinc. Virtually the entire output was exported in 1963, in the form of hand-picked lead ore containing 40 to 45 percent lead, mostly to West Europe. Zinc ores went to domestic consumers as did an estimated 10,000 tons of imported zinc metal and alloys. Imports supplied several galvanizing plants in Bangkok. A large oxide deposit, the Mae Sot in Tak Province, stayed unmined, although a Japanese company, Sumitomo Metal Mining Co., Ltd., maintained an interest in it.

Manganese.—Output of manganese ore, better than half of which was battery grade, more than doubled the 1962 level in response to increased demand by Bangkok's growing dry-cell-battery industry and the export trade, largely to Hong Kong. Until late 1961 most ores had been produced at the Huai Muang mine, Loei Province; subsequently, a second potentially larger mine, the Ban Mae Jong, started up in Lampoon Province. Another manganese discovery in the southern jungles near the Kumoon River was being readied for production in 1963 by Nara Mining Co., Ltd., Thai subsidiary of a Malayan company, Ma-Thai Mining Corp., Ltd. The deposit was estimated to contain over 250,000 tons of ore, one-fourth of which was high-grade.

Tin and Tungsten.—Tin output was 6 percent higher than in 1962. While rising steadily, output was still below the record 17,400 tons of tin-in-concentrates established in 1940. Several hundred tons of tin metal were produced in a pilot reverberatory furnace smelter (1,000-ton-tin-metal-yearly capacity) operated in Bangkok by the Department of Mines for meeting the bulk of domestic tin needs. During 1963 tin exports, all in the form of concentrates and averaging 73.25 percent tin, rose 10 percent in tonnage and 9.5 percent in value to US$35.7 million. Concentrates were exported mainly to Penang in Malaya and the Netherlands.

Digitized by Google

Approximately 24 bucket dredges, mainly British owned and operated, produced half of the tin, lode mines less than 5 percent, and most of the rest came from gravel pump and hydraulic mining. As many as 400 individual mine units were worked in 1963. By far the richest tin area was peninsular Thailand from Ranong south to the island of Phuket that provided over 80 percent of the national output. Offshore deposits near Phuket accounted for about one-fifth of all tin production.

Three companies had dredges working in Phuket Bay: Ao Kam Tin, Ltd., Tong Kah Harbour Tin Dredging, Ltd., and Ngan Tavi Bros. (Nai Chaisin), Ltd. Ao Kam operated a converted oil-tanker grab dredge and was rebuilding a 110-foot-digging-depth bucket dredge from Tronah Mines for seagoing duty. These two dredges were due to start work off the west coast of Phuket Island on the Bang Tao Bay properties acquired from Tromal Prospecting, Ltd., where deposits were estimated to total 32 million cubic yards averaging 0.626 pounds of tin concentrates per yard. Tong Kah Harbour purchased nine mining leases adjoining its Outer Harbour leases thus extending its sea dredge's life about 3 years. Average grade though was expected to be substantially lower than in the sea leases being worked.

Thai Smelting & Refining Co., a joint venture of Union Carbide Ore Co. (United States) and Eastern Mining Development Co., Ltd. (Thailand), proposed to build a 10,000- to 15,000-ton-tin-metal-per-year smelter costing about US$6 million on Phuket Island. Such a smelter had been under consideration for some years as part of the Government's promotion of industries program. Although the decision to build appeared firm, the project was delayed while negotiations were being completed. Union Carbide was also engaged in another venture in which offshore deposits extending southward from Ranong into Phuket Bay were to be prospected for tin.

Although no production of heavy mineral sands was recorded large tonnages lay potentially recoverable in tin mine tailings and dumps. The Department of Mines as well as private companies—Thai Sin Chan Co. for one—sought markets and studied upgrading methods. Lack of an ilmenite market was a basic problem. Thai Sin had stockpiled about 150 tons of monazite and 40 tons of 20 to 40 percent columbium-tantalum concentrates in 1963.

Tungsten concentrates averaging about 65 percent WO_3 were mainly the byproduct of tin mining, and totaled less than half of the 1962 output, while exports gained about 20 percent. Probably some production still came from once-important lode mines in northwestern Thailand's Ban Mae Sariang district, Mae Hong Son Province, and the Pilok district, Kanchanaburi Province, where deposits were being worked mainly by tributers. Low tungsten prices, difficult access, and restrictions on foreign company operations in the area north of the 10°-latitude line combined to discourage lode mining activity.

NONMETALS

Cement.—Two companies produced Thailand's entire 1963 output of cement, which was 3 percent more than in 1962. The larger, Siam Cement, Ltd., operated a 4-kiln wet process plant at Tha Luang, near Saraburi, and a 2-kiln plant at Bangsue, Bangkok. Although rated

Digitized by Google

capacity was 800,000 tons, the company produced 836,000 tons in 1963, about 618,000 tons going to the domestic market and the rest exported. A fourth mill was being installed at Ta Luang; meanwhile, surplus cement clinker was shipped by barge to the Bangsue plant for finishing. Construction of a new plant with 300,000 tons capacity was scheduled by the company to begin in 1964 at Tungsong, southern Thailand.

The Royal Irrigation Department-operated plant of Cholprathen Cement Co. at Talki, Nakon Sawang, built mainly to supply cement for the Yan Hee power project, produced 160,533 tons of cement in 1963. Since dam construction was nearing completion, other potential markets were sought.

Domestic sales of cement in 1963 totaled 759,444 tons value at about US$17.3 million. Exports were 22 percent less than in 1962 and went mostly to South Viet-Nam under U.S. Operations Mission procurement.

Fluorspar.—Fluorspar production, beginning in 1960 after discoveries in the Ban Phu Krood (Khao Chom Thai) district, Rat Buri Province, and the Doi Tai district, Chiang Mai Province, rose to 29,230 tons in 1963. Handpicked ore grading 80 to 85 percent CaF_2 was produced for export, with Japan the main purchaser. India reportedly received 2,920 tons of Thai fluorspar, nearly one-third of its needs in 1963. Most if not all 1963 production was from the Ban Phu Krood deposits mined by Siam Ore Co., Ltd. Only about half of the output was exported, and the rest apparently stockpiled awaiting markets or perhaps transportation since access was difficult in the back country.

Gem Stones.—Gem stone deposits along the Burma border and in southeast Thailand have been important sources of sapphire, ruby, topaz, zircon, and spinel, but since the loss of natural stone markets to synthetics, mining has been sporadic with no production recorded. However, gem cutting is $1-million-yearly industry in Bangkok, largely due to the good labor market, and a sizable trade goes on in cut and uncut stones; the value of 1962 exports was about US$1.2 million, compared with imports of US$130,000. Switzerland and the Republic of South Africa supplied most of the uncut gems, largely synthetic, and the United States and West Germany were the main customers for cut stones.

Gypsum.—Thai Gypsum Co., Ltd., produced high-quality and high-cost gypsum from its Dammern mine, near Lampang, with nearly all of the output going to the cement industry. The company was scheduled to complete a 16-ton-feed-per-day gypsum products plant in 1963, and plans were being considered for plasterboard manufacturing. A sizable deposit was being mined, with a 90-foot thickness of gypsum overlying 30 feet of anhydrite.

Salt.—Sea salt was produced at widely scattered coastal points by thousands of individual Thai "salt farmers," the main production coming from the north coast of the Gulf of Siam. Output had been falling and hit a low of 150,000 tons in 1962 but rose to 200,000 tons in 1963. Poor production was attributed to lack of foreign demand (usually about two-thirds of the output was exported) and availability of better grade salt elsewhere. Much of the Japanese market in particular had been lost because of Thai salt's high water content

Digitized by Google

(nearly 9 percent). Studies were being made at an experimental saltern set up by the Department of Science seeking better salt farm methods and moisture reduction.

What could prove to be one of the world's great rock salt deposits has been discovered on the Khorat Plateau, in southeast Thailand.[3] The area was first explored in 1955 after the salt was intercepted during drilling under a U.S. Operations Mission ground water exploration program. Salt reserves were roughly estimated at 3 billion tons, assuming an average thickness of 100 meters, with depth to top of salt generally 300 to 500 feet. The Royal Department of Mines continued a program of geologic studies in the area.

MINERAL FUELS

Lignite.—Lignite was mined in 1963 at Mae Moh, near Lampang, in northern Thailand, and processed in one 1,200-ton-per-day plant provided by Australia in 1961 under the Colombo plan. Coal went to the 12,000-kilowatt Mae Moh powerplant, to the Tha Luang cement plant, and some to consumers in the Bangkok area, including the northern Bangkok powerplant. Coal transportation was improved in 1962 when the Australian Government furnished 100 rail hopper cars through the Colombo plan. In southern Thailand, deposits containing an estimated 5.5 million tons of lignite were being developed to supply the nearly completed Krabi powerplant with 600 tons of coal daily.

Owing to rapid rise in price of charcoal (quoted at US$2.25 per hundredweight in mid-1963), an important Thai fuel, interest was renewed in a Husky Oil Co. (United States) process for briquetting lignite, and plant feasibility studies were recommended. Possibilities were discussed for using Thai lignite to produce nitrogenous fertilizers,[4] and although proposals had been offered by both Standard Vacuum Oil Co. and a West German firm to construct such a plant, the Government delayed approval pending further studies.

Oil Shale.—An oil shale project, to include a US$30 million to US$35 million refinery, was being considered as a joint venture by Japanese and American investors. The plant, probably to be located at Tak, would process shales with fairly high oil content from the Mae Sod field, overlapping the Burma border near Moulmein. Byproducts would include coke, ammonium sulfate, and hydrocarbon gas.

Petroleum.—Consumption of petroleum products in Thailand was estimated at 35,000 barrels per day (13 million barrels yearly) in 1963, about 9 percent higher than in 1962 and 43 percent above that of 1960.[5] Nearly all requirements were imported, mainly from Indonesia and partly from Iran. Probably 90 percent or more of the imports entered the country through the port of Bangkok, and these were valued at US$50 million in 1963.

The country's only crude oil was produced by the small Farng Basin field in northern Thailand at 100 to 125 barrels per day and processed

Digitized by Google

in the overbuilt Farng refinery rated at 1,800 barrels per day. Established on wishful promise of discoveries and operated since 1959, the refinery ran only a few days a month as sufficient oil became available. In July 1963 a new exploratory well struck oil at a depth of 2,200 feet flowing about 30 barrels per day. This was followed by 9 other holes; 2 hit oil at 5,000 feet, 1 flowing 25 barrels per day while the other just oozed. The new-found oil was lighter than that previously discovered, had a high wax content, and was expected to require different processing, perhaps involving major plant revisions. The combined 1963 crude production and refinery throughput were estimated at 45,000 barrels.

Over 1 million barrels of crude or partly refined oil was imported from Saudi Arabia; in 1962 there were no unrefined imports. A 3,000-barrel-per-day refinery operated by Thai Asphalt Manufacturing Co., at Sriracha, on the Bay of Bangkok 75 miles southeast of Bangkok, apparently was the recipient.

Thai Oil Refining Co., Ltd., a consortium of West Europe and United States companies, was completing a US$33 million, 36,000-barrel-per-day refinery at Sriracha. Scheduled for operation in August 1964, this refinery, the largest on the southeast Asia mainland, would have overall capacity roughly equal to domestic consumption. Shell International supervised construction, was to supply the crude, and operate the plant for a management fee. Although basically a private enterprise, the refinery was to pay the Government one-fourth of yearly net profits and relinquish ownership after 10 years.

A US$18 million, 5,000-barrel-per-day Government refinery at Bangchak, near Bangkok, scheduled for completion in 1962 was still unfinished at the end of 1963. Its small size and expense cast doubts about economic operation. Contractors had received their fourth extension and a new deadline of April 1, 1964. Esso signed a 2-year contract to supply the plant with 3.3 million barrels of crude from the Middle East. Products were to be distributed by the Oil Fuel Organization of the Military Energy Department, Ministry of Defense.

Union Oil Co. of California was granted a 5-year concession to explore about 21,000 square miles of the Khorat Plateau in northeast Thailand, south of the Mekong River, and planned an oil survey to begin in late 1963.[6] Monet Knock, a California-based company, acquired a concession to survey a small area of the Ubon district in the northeast.

The Mineral Industry of North Viet-Nam

By K. P. Wang [1]

NORTH VIET-NAM, with about 16 million people, inherited the bulk of French Indochina's mineral wealth. Great emphasis has been placed on basic industries by the Vietnamese Communists, as shown by the projects undertaken in the 1958–60 plan and the 1961–65 5-year plan. As a result, the relative importance of industry in North Viet-Nam's economy reportedly had increased about 150 percent in 1961 compared with 1955. The share of mineral contribution to industry is hard to assess, however, North Viet-Nam's 1963 mineral output value of approximately US$90,000,000 was more than that of any other country in the Malayan Archipelago except Malaysia.

North Viet-Nam has been producing an increasing variety of mineral products from its promising mineral potential, however, only a few items were significant by international standards. The country's anthracite has been well known in oriental markets, particularly in terms of quality. Production of phosphate ores in 1963 was about 1.5 percent of the world total. The third product of some consequences during the year was high-grade metallurgical chromite, perhaps 1 percent of the world supply.

Under the present low-consumption conditions, the country has a fairly strong mineral self-sufficiency position. Additional mineral resources exist and can be developed as industrialization advances. Large iron deposits have been discovered; a variety of nonferrous metals exist in commercial quantities; and chemical and fertilizer resource base is good. Construction materials can be developed according to need, and many useful nonmetallics occur. However, there is little coking coal, the abundant mineral fuel being anthracite. So far, petroleum is entirely lacking. Fuel deficiencies are compensated by hydropower potential. North Viet-Nam produced about 440 million kilowatt-hours of electricity in 1963.

The most important mineral development during 1963 was in the field of iron and steel. The first blast furnace of the newly created Thai Nguyen integrated steelworks built with Chinese Communist assistance was completed, and a mine supplying the necessary iron ore became a commercial operation. Apatite mines were being greatly expanded to meet primarily foreign demand, and additional chemical fertilizer facilities were completed. During the year, the Ru-

[1] Chief specialist, East Europe–Far East, Division of International Activities.

Digitized by Google

manians were engaged in building a new section of the Haiphong Cement Plant. The Hon Gay-Cam Pha anthracite district was being readied in 1963 for a large increase in production; exports to Western Europe were greater in 1963 than in previous years.

PRODUCTION

Mineral output value of North Viet-Nam roughly doubled between 1959 and 1963. Ores and concentrates still constitute the main type of nonfuel mineral products, but ground work has been laid for making mineral and metal products. About one-third of the 1963 total mineral output, including fuels, was exported.

Coal, primarily anthracite, was by far the most important mineral product in 1963, accounting for more than half of the total output value. Cement represented possibly one-sixth, followed by apatite which has steadily gained in relative significance. Metals and metallic ores were not yet important, but future emphasis was clearly indicated.

In addition to commodities for which production statistics are available or for which estimates of production have been made, many other items are known to have been produced in 1963, including 20,000 to 30,000 tons of cast iron and steel, probably more than 100,000 tons of iron ore, 400 to 500 tons of refined tin, thousands of tons of zinc concentrate, significant amounts of gold, large quantities of ordinary clay for brick and tile, 1,000 to 2,000 tons of kaolin for ceramic use, some 50,000 tons of dolomite, 20,000 to 30,000 tons of glass sands, a modest quantity of pyrite, and some asbestos and mica. Systematic extraction of lead, antimony, copper, manganese ore, and mercury was about to commence.

TABLE 1.—Production of minerals and metals [1]

(Metric tons)

Commodity	1959	1960	1961	1962	1963 [2]
Metal:					
Chromite	6,600	19,400	29,500	32,600	32,000
Nonmetals:					
Apatite	260,600	490,000	563,600	678,000	750,000
Cement	381,200	408,000	457,500	462,000	500,000
Phosphate rock	50,800	51,000	58,100	34,000	50,000
Salt	130,000	117,100	106,100	144,000	150,000
Mineral fuels:					
Coal [3]	2,201,700	2,595,000	2,829,400	3,468,000	4,000,000

[1] In addition to commodities listed, North Viet-Nam is known to have produced the following commodities: Gold, iron ore, cast iron, steel, refined tin, zinc concentrates, asbestos, clays (for brick and tile), dolomite, glass sand, kaolin, mica, and pyrite.
[2] Estimate.
[3] Predominantly anthracite.

TRADE

Since official trade statistics are not available for North Viet-Nam, details on mineral exports are not clear. However, based on imports of other countries, anthracite exports are significant, Japan alone having imported 651,895 metric tons in 1962 and 475,704 metric tons

Digitized by Google

in the first 11 months of 1963. The Soviet Union and Japan took respectively 118 long tons and 153 long tons of refined tin from North Viet-Nam during 1961–62; Czechoslovakia was also among tin importers in 1963. Japan obtained 12,900 metric tons of salt and 747 metric tons of phosphate rock from North Viet-Nam in 1962. Mainland China acquired sizable tonnages of North Vietnamese apatite, anthracite, and chromite in recent years. However, Rumania and Poland have been the main purchasers of apatite.

Soviet mineral exports to North Viet-Nam are presented in lieu of official Vietnamese imports, recognizing that Japan and mainland China are also suppliers although of lesser consequence. Principal Soviet shipments have been in two main categories, petroleum and metal products. No doubt the Soviet Union was North Viet-Nam's main source of petroleum, there being none produced locally. Soviet supplies of rolled steel products were essential, but North Viet-Nam is building a small steel industry and imports tinplate from Japan and other steel products from mainland China. Nominal amounts of nonferrous metal products have been imported for some years from these three countries.

TABLE 2.—Imports of metals and minerals from the Soviet Union [1]

(Metric tons)

Commodity	1961	1962	Commodity	1961	1962
Metals:			Metals—Continued

COMMODITY REVIEW [2]

METALS

Chromite.—During recent years, North Viet-Nam has developed a fair sized stabilized chromite industry, capable of producing 30,000 to 35,000 metric tons of high-grade alluvial concentrate per year. There is only one mine—Co Dinh—located amidst the Nong Cong ricefields, 30 kilometers from Thanh Hoa. The chromite occurs as placers in the Malayan Peninsula and is mined in a manner similar to some tin operations. Information in 1963 indicated the use of hydraulic monitors and water troughs. All told, there were about 2,000 workers mining chromite. North Viet-Nam's chromite was shipped to the Soviet Union and to mainland China during 1963.

[2] U.S. Department of Commerce. Mineral Reserves in North Viet-Nam. Office of Tech. Services, JPRS 17769, North Viet-Nam Economy No. 40, Feb. 21, 1963, pp. 22–25.

Digitized by Google

Iron and Steel.—North Viet-Nam's almost complete dependence on foreign iron and steel products may come to an end in a few years' time. Construction on a new 200,000-ton iron and steel complex at Thai Nguyen, 75 kilometers north of Hanoi, began in September 1960, and the complex is now taking shape. The first of two blast furnaces was commissioned in December 1963, and the plan is to complete the whole project by 1966. A 24,000-kilowatt powerplant was already supplying power to the steelworks as well as to the cities of Hanoi and Viet Bac. The nearby Tri Cau iron mine, with an initial 300,000-ton annual capacity and 10 to 60 million tons of high-grades reserves, started to furnish ore to Thai Nguyen late in the year. Several small cast iron and steel plants were in operation during 1963, partly using anthracite as fuel.

Other iron deposits were reported in 1963, the most promising being Bao Ha, said to be capable of supporting a second iron and steel complex in North Viet-Nam.

Tin.—North Viet-Nam's 1963 refined tin output estimated at 400 to 500 metric tons was derived primarily from facilities in the Tinh Tuc district near the Chinese border in Cao Bang Province. Tinh Tuc has a smelter with annual capacity exceeding 1,000 tons of 99.75 to 99.85 grade refined tin.

A dozen properties with promising reserves surround Tinh Tuc, a fairly modern open pit mine as of 1963, which was equipped with Soviet excavators, Czech trucks, and locally made rolling stock. A light railway connects the mine with the nearby refinery, and electric power is supplied by a small hydroelectric plant. Resuming operations in 1955, Tinh Tuc began to produce at relatively high levels only since 1958. Recent information on North Viet-Nam's tin industry has been spotty. Available output and trade data are tabulated below, in metric tons of refined tin:

Year	Output	Japanese imports	Soviet imports	Year	Output	Japanese imports	Soviet imports
1955	15			1959	(1)		36
1956	50			1960	[2] 430	155	45
1957	104		(1)	1961	(1)	110	40
1958	223		(1)	1962	(1)	45	80

[1] Data not available.
[2] Target.

Other Metals and Metallic Ores.—No recent reliable reports on the status of North Viet-Nam's zinc industry are available. There was once a 6,000-ton horizontal retort smelter at Quang Yen and a mine at Cho Dien in Bac Kan capable of fully supplying the smelter with calamine concentrate containing 40 percent zinc. As of 1963, it appeared that the smelter had not been reactivated but zinc concentrate, possibly on the order of 10,000 tons per annum, was produced at Cho Dien. A second zinc mine, the Mo Thiec operation in Cao Bang, was also in operation.

North Viet-Nam has many small lead deposits, and one deposit at Tu Le of Yen Bai with lead-zinc ore may be fair-sized. Scores of copper showings have been discovered in recent years, the most

Digitized by Google

promising deposit reportedly being Me Kien in the northeast mountain area. Antimony deposits have been discovered at Bong Mie and Ta Soi in Thanh Hoa and elsewhere. Mercury is found in Ha Giang, and manganese ore in Ha Tinh. Bauxite occurs in Lang Son and near Haiphong, but known reserves are small and the grade is generally low. Few of these findings have been worked on a systematic basis. However, gold was produced on a commercial scale in 1963 at the Tso-pien mine of Hoa Binh, the Tso-lung mine of Bac Kan, the Tinh Tuc tin mine, and elsewhere.

NONMETALS

Cement.—Haiphong, North Viet-Nam's only cement plant of note in 1963, had about 500,000-ton annual capacity. The Rumanians are helping to build a new section which, when completed in 1965, will have an additional 700,000-ton capacity. Because of the rapidly growing demand for cement, a number of small vertical kiln plants have also been constructed in recent years including Nghe An and Sai Son. Even Haiphong, whose four main kilns are of the horizontal rotary type, was reactivating its 2.5-meter-diameter vertical kilns in 1963. North Viet-Nam's cement plants are anthracite-fired, but the use of low grade coals was being investigated. The country sells a little cement to Cambodia.

Glass Sand.—The country's second glass plant (the first is at Hanoi) was completed in Haiphong during 1963 with the help of East Germans. The glass sand for these plants came from Van Hai in Hong Quang and elsewhere. The Haiphong plant may need about 20,000 tons of glass sand annually.

Phosphates.[3]—North Viet-Nam's phosphate industry comprised mainly of apatite facilities but with lesser phosphate rock mines and phosphatic fertilizer plants of different kinds, achieved notable success in 1963. Apatite output (probably about 35-percent P_2O_5 grade) surpassed 700,000 metric tons for the first time, and the 1965 plan was to double this tonnage. The 100,000-ton Soviet-equipped Lam Thao superphosphate plant finally attained regular production status. Surplus North Vietnamese apatite was exported to Eastern Europe and mainland China during the year.

All apatite came from the Laokay (or Lao Cai or Cam Duong or Lao Kay) mine in the northeast where reserves have been variously estimated at 300 to 1,000 million tons of 10- to 40-percent P_2O_5 ore. Development of mine and railroad to Haiphong has been under the direction of Rumanians who hope to get 630,000 tons of apatite yearly by 1965 for the credit and technical aid extended. Laokay mine had electric and diesel power shovels working rich zones of pits and some 50 trucks moving the material to railroad in 1963.

The Lam Thao superphospsate plant, designed to use about 60,000 tons of apatite yearly, is the first of several such plants to be built. It has a 40,000-ton sulfuric acid unit and produces 20- to 21-percent P_2O_5 grade superphosphate. The phosphate rock mines near Ham

[3] U.S. Department of Commerce. Changes in the Lao Kay Apatite Mine. Office of Tech. Services, JPRS 22255, North Viet-Nam Economy No. 74, Dec. 13, 1963, pp. 46–51.

Digitized by Google

Rong and Vinh Tinh in the north-central district and their corresponding processing plants (ground and chemical phosphates) apparently had operating difficulties during 1962–63.

Salt.—North Viet-Nam's sea water salt output exceeded 150,000 tons per annum for the first time in 1963. Nam Dinh is the leading field, providing nearly half of the national output. Small scale solar evaporation methods, most using hand labor are used. Recent efforts to raise salt production have centered around consolidation of operations, basic construction, and planning technical measures for year-round business. Some surplus salt went to Japan during 1962–63.

MINERAL FUELS

Anthracite.—Anthracite is by far the most important mineral commodity produced in North Viet-Nam. North Vietnamese anthracite is not only indispensable in the industrialization program, but also important as an export item. In 1963 more than 1 million tons were exported, about one-half to Japan and 10 to 15 percent each to France and the Netherlands. A sizable tonnage also went to mainland China, and lesser amounts went to Italy and Hong Kong. North Vietnamese anthracite commanded a price of $12 to $15 per metric ton f.o.b.

During the year, the Hon Gay-Cam Pha District, with reserves exceeding 1 billion tons and with about 20 mines including three large pits in operation, clearly retained its position as the foremost anthracite district in North Viet-Nam. The coal is 20 to 80 meters thick, usually occurring near the surface. Crushing and sorting are done at the mine site, whereas grading is carried out at the port of Cam Pha where more than 10,000 tons can be handled daily and at least four 12,000-ton ships can be loaded simultaneously.

An important project for the Hon Gay enterprise during 1963 was to raise the proportion of lump coal from about 25 to 30 percent so as to derive more income. Overburden was stripped in preparation for expanded production. Methods were devised to raise the efficiency of drilling and blasting, better the development and operation of pits, improve equipment maintenance, streamline transport, and make best use of available equipment.

The Mineral Industry of South Viet-Nam

By J. M. West[1] and K. P. Wang[2]

SOUTH VIET-NAM is far less richly endowed with mineral resources than neighboring Communist North Viet-Nam. The only mineral products of any consequence produced in South Viet-Nam in 1963 were coal, salt, and silica sand. Value of output was an insignificant part of the estimated US$1.4 billion gross national product. Continued Vietcong guerrilla activities limited mineral exploration. Many areas were insecure. There was little mining except for coal at Nong Son in the north, where capacity was being expanded to meet future demands of a large coal-based chemical and nitrogenous fertilizer manufacturing complex to be built at An Hoa, an industrial site near the mine.[3]

Since four-fifths of the country's 15 million people derive a livelihood from agriculture, the government has been particularly interested in developing fertilizers. The An Hoa facilities together with a phosphate fertilizer plant planned at Tan Thuan, near Saigon, were expected to supply 30 percent of the country's fertilizer requirements by 1966.[4] The Tan Thuan plant, with capacity of 48,000 metric tons per year of phosphate products, would process phosphate rock from deposits being developed on the Paracel Islands, South China Sea. A plant proposed for Chanh Hung, near Saigon, would make fertilizer from city refuse, processing about 10 tons per day. Nhatrang was scheduled to receive an oil refinery.

Shortages of electrical power handicapped industrial growth. Construction of a 33,000-kilowatt thermal powerplant, to burn coal from Nong Son, was started at Thu Duc, a few miles north of Saigon. First power from the Japanese-built 160,000-kilowatt Da Nhim River hydroelectric project near Phan Rang, northeast of Saigon, was delivered on a trial basis to a substation at Thu Duc in December 1963; generators with capacity totaling 80,000 kilowatts were in service at yearend, together with 155 miles of transmission lines to the Saigon area.

GOVERNMENT POLICIES AND PROGRAMS

The government issued a new investment law (retroactive to January 1, 1963) guaranteeing all business enterprises protection from nationalization for 12 years and providing for repatriation of original investment after this period. Foreign enterprises were exempted

from taxation on profits during the first 3 years of operation. Firms were allowed to employ foreign technicians.

PRODUCTION

Mineral production included coal, salt, silica sand, and a small quantity of china clay. The coal was mined from the Nong Son deposit near Tourane (Da Nang); salt produced by evaporating sea water was recovered from salinas along the central and southern coasts, and silica sands were excavated in the Baria region near Cap St. Jacques and the port of Saigon. Large quantities of briquets were produced. Although information was lacking, at least part of the briquets were composed of Nong Son coal with a clay binder.

TRADE

South Viet-Nam depended on foreign sources for all supplies of iron and steel, petroleum products, chemical fertilizers, cement, and miscellaneous metals. Minerals accounted for 10 to 15 percent of all South Viet-Nam imports in 1962. Imports of iron and steel during the first 10 months of 1963 totaled 153,406 metric tons, indicating a sizable increase over the 78,840 tons reported for the same period of 1962. Imports for 1963 may be about 180,000 metric tons. No data are available on petroleum imports for military purposes. The civilian market was supplied mainly by oil from Indonesia. Imports of all types of fertilizers were estimated at 220,000 metric tons in 1963, nearly double the total of 115,554 tons in 1962. Of 103,085 metric tons of phosphate fertilizers imported in 1963, 71,103 tons were from Tunisia and 27,644 tons were from the United States. Taiwan was the principal source in 1962–63 of urea, industrial chemicals, cement, and aluminum and supplied about one-third of all iron and steel mill products. Anthracite imported from the United States was mixed with higher ash domestic coals and burned in Saigon area powerplants.

In 1962, Japan imported 20,250 metric tons of salt and 94,294 tons of silica sand from South Viet-Nam. Silica sand shipments received by Japan were 80,065 metric tons in 1961 and 46,476 tons in 1960.

COMMODITY REVIEW

METALS

Iron and Steel.—During 1963 the Industrial Development Center of Viet-Nam, a government agency, invited foreign bids to supply and invest in a steel-rolling mill with 25,000 metric tons annual capacity of reinforcing bars and rods.[5] Association for Development Assistance, Inc., a Pittsburgh firm, was employed by the Agency for International Development (AID) to make a feasibility study for an iron and steel and/or metalworking plant. This represented South Viet-Nam's first serious effort to build a steel plant.

Lateritic iron ore samples were collected at several sites in Quang Ngai Province and sent to the U.S. Bureau of Mines for analysis during 1963. Samples were found to contain 18 to 59 percent iron. No information was received to indicate extent of the deposits.

NONMETALS

Asbestos.—A new asbestos-cement products plant was scheduled to begin operation in 1963 in the Bien Hoa industrial zone. Imported asbestos was required because no domestic material was available.

Caustic Soda and Chlorine.—Viet-Nam Chlorine & Alkali Co., a private venture, planned to use locally produced salt in making caustic soda (1,080 metric tons per year) and chlorine (930 metric tons per year) by electrolysis at a plant to be constructed on the Dong Hai River near Saigon. The plant was scheduled for operation in 1963.

[5] International Commerce. Steel Rolling Mill Planned in South Viet-Nam. U.S. Department of Commerce, v. 69, No. 42, Oct. 21, 1963, p. 28.

Digitized by Google

Cement.—Grinding operations in the Thu Duc section of the French-built Ha Tien-Thu Duc cement plant started in November on a trial basis using imported clinker. The clinker-producing portion of the plant, at Ha Tien on the Gulf of Siam, was expected to begin operation about yearend. Its capacity of about 300,000 metric tons was adequate to supply three-fourths of 1963 domestic demands. Clinker would be shipped by barge to Thu-Duc for finish grinding. There was no report on progress in construction of the Long Tho cement plant in Thua Thien Province, which had been delayed in 1962 pending a decision to raise its planned capacity from 25,000 to 60,000 tons annually.

Sand.—Sand from the Baria region near the port of Saigon was used by the Vietnamese Glass Corp. (completed in 1960) for making a variety of glassware including laboratory equipment. The plant's yearly capacity was estimated at 20,000 metric tons. Most of South Viet-Nam's glass sands, which are of very high quality, have been sold to Japan during recent years.

Sulfur.—A proposal was studied to establish a sulfuric acid plant, to be supplied initially with imported sulfur and later with byproduct sulfur produced by the proposed Nhatrang refinery. An aluminum sulfate plant which would require imported aluminum hydrate was proposed simultaneously.[6] The demand for aluminum sulfate was mainly for water treatment and in the paper industry. Proposed capacity of the acid plant was 4,200 metric tons per year, of which 1,445 would be used to produce aluminum sulfate, leaving a surplus of acid for other purposes.

MINERAL FUELS

Coal.—Contracts were signed early in 1963 with French and German firms to begin the first stage of construction on an industrial complex at An Hoa, about 40 miles southeast of Tourane, which would consume coal from the nearby Nong Son deposits. The development was to include plants for producing thermal electric power, sulfuric acid, urea (42,000 metric tons per year), ammonium sulfate (48,000 tons), and calcium carbide (8,000 tons), and plants to manufacture gas from coal, liquefy air, and synthesize ammonia. The calcium carbide plant would supply a calcium cyanamide plant (8,000 metric tons per year) scheduled for a second stage of construction. The Nong Son mine was under intensive development, and studies by the Paul Weir Co. (Chicago) under an AID contract resulted in coal reserve figures being increased from 3 million to 4 million tons at the beginning of 1963. After reopening the mine in 1957, production rose to 71,000 metric tons in 1962 and was scheduled to jump to 150,000 tons in 1963. With output at only 95,000 tons in the first 11 months of 1963, the year's total was expected to fall considerably short of the goal. A washing plant built with French aid in 1960–61 was operating, and a rail spur connected from a point near the mine to the main north-south railroad.

Petroleum.—Since there were no domestic petroleum resources all of the country's requirements were imported. A contract signed in April

1962 by Esso Standard Eastern, Inc. (successor to Standard Vacuum Oil Co.), Shell Co., Viet-Nam, and the Government provided for construction of a refinery on the coast at Nhatrang with sufficient capacity to meet projected demands by 1968. Initial production was scheduled early in 1965. Travel restrictions due to security problems caused sales of motor fuels to decline, while increased air traffic resulted in increasing consumption of jet fuel and aviation gasoline.

The Mineral Industry of Australia

By Lester G. Morrell [1]

UPTREND in value of mineral production in the Commonwealth of Australia continued in 1963, again pacing the country's general economic growth rate. Increases occurred in output of most raw and processed mineral products, including bauxite, copper, iron ore, pig iron, steel, lead, zinc, cement, gypsum, pyrite, coal, and refined petroleum products.

Although the economy of Australia has been traditionally based on wool and agricultural products, in recent years the country has become highly industrialized. Nearly one-third of the 3.6 million total civilian labor force is engaged in manufacturing. Employment in mines and quarries occupies 1.4 percent of the national labor force.

The value of mine and quarry products in 1963 has been estimated at A£205 million.[2] This is the highest on record and represents a threefold increase since 1950. Expansion in the minerals industry has kept pace with the overall national economic growth as indicated by rise in gross national product (GNP) from A£2.7 billion in 1950 to A£7.8 billion in 1963. Although the ex-mine value of minerals has amounted to only 2.5 to 3.0 percent of the GNP, primary and secondary processing, manufacture of finished products from domestic raw materials and supply as well as communications and transport services—all add up to a far greater relative importance.

Absolute value of Australia's mineral products on the basis of mine output and including initial processing such as milling, smelting, or refining in Australian facilities has been estimated for recent years as follows:

Year	Mine output value		Total value including domestic primary treatment	
	Million Australian pounds	Million U.S. dollars	Million Australian pounds	Million U.S. dollars
1959	165	370	214	479
1960	181	405	234	524
1961	181	405	238	533
1962	192	430	256	573
1963	205	459	285	638

In 1962, the most recent year for which detailed data are available, metals accounted for 38.5 percent of the total ex-mine output. Non-

[1] North America-South Pacific specialist, Division of International Activities.
[2] One Australian pound (A£1) = US$2.24.

Digitized by Google

metals included 16.7 percent construction materials and 9.7 percent industrial minerals. Coal made up the remaining 35.1 percent. Black coal has traditionally been Australia's most valuable mineral product, accounting for nearly one-third of the national total. The 10 principal product categories in 1962 in percentage of total national value were: Black coal 31.0, construction materials 16.7, copper 12.8, lead 10.2, gold 8.2, brown coal 4.1, iron ore 2.8, zinc 2.4, limestone 2.0, and titanium concentrates 2.0. The base metals values include contained silver which, if considered separately, would approximate 5.0 percent of the national total.

The value added to mineral products as a result of treatment has ranged from about A£49 million in 1959 to A£64 million in 1962 and to an estimated 80 million in 1963.

Generally, over half of the total addition results from processing of iron ore. The value added to various mineral commodities through primary treatment in 1961 and 1962 in millions of Australian pounds is condensed as follows:

	1961	1962		1961	1962
Copper concentrate	4.1	5.6	Iron ore	35.4	39.0
Lead concentrate	7.3	6.8	Bauxite	--	.5
Zinc concentrate	9.6	11.5			
Tin concentrate	.5	.5	Total	56.9	63.9

Among the free world countries, Australia is the leading producer of lead (mine basis) and of rutile; it is an important supplier of ilmenite, monazite, zinc, silver, and beryl. As a result of recent discoveries and developments, Australian iron ore, bauxite, and possibly alumina, may also become important in future years.

Domestic resources supply many of the minerals required by Australia's consuming industries. National self-sufficiency exists in crocidolite asbestos, barite, bauxite, cement and other construction materials, copper, lead, zinc, the precious metals, iron ore, manganese, tungsten, and salt. More than half the required diatomite, ferroalloys, magnesite, elemental sulfur and tin are also domestically produced. Among Australia's principal deficiencies are petroleum, phosphate and other fertilizer materials, fluorspar, nickel, and chrome ore.

The outstanding mineral developments in the 1962–63 period revolved around earlier discoveries of iron ore in the Pilbara region of Western Australia, and the bauxite occurrences on both Cape York and Gove Peninsulas on the northern tips of Australia. Several new production records were attained in 1963, notably in iron ore, pig iron, steel, ferromanganese, bauxite, lead ore, and silver. And following many years of exploration, the Moonie field in Queensland was brought in as Australia's first petroleum producer. A pipeline to carry the field's output to Brisbane was completed in 1963.

GOVERNMENT POLICIES AND PROGRAMS

New minerals legislation enacted in 1962 and early in 1963 applied primarily to taxation. The Income Tax and Social Services Con-

Digitized by Google

tribution Assessment Act 1962 provides moderate benefits in taxation on new mills and processing facilities. The Gold Mining Industry Assistance Act was extended for a further 3 years from July 1, 1962. Further modifications were applied in June 1963 to the 1960 relaxation of iron ore export controls. Since June 1963, export of any iron ore deposit containing less than 5 million long tons has been authorized. Amendments announced in 1963 to the Income Tax Act provide for deductions in respect to expenditures on rights to prospect or exploit petroleum and on certain types of technical information related to petroleum concessions.

The Bureau of Mineral Resources, Canberra, and the various counterpart State agencies, the Commonwealth Scientific and Industrial Research Organization (C.S.I.R.O.), the Australian Mineral Development Laboratories, and the Australian Atomic Energy Commission all render technological assistance to the minerals industry. The New South Wales and Queensland coal industries are assisted by the Commonwealth through, respectively, the Joint Coal Board and Queensland Coal Board. Through Subsidy Acts, the Commonwealth Government has financed part of the nationwide search for petroleum and rendered direct assistance to the gold mining industry. Assistance in the form of a tariff and bounty is paid to producers of copper; and under a 1962 provision, bounty benefit is now extended to include copper and brass strip manufactured for Australian consumption. The Pyrites Bounty Act and the Sulphuric Acid Bounty Act provide bounty payment for these products from certain indigenous raw materials.

Export controls are exercised on beach sands and minerals containing zircon, titanium, lithium, beryllium, manganese and iron ores, fertilizer materials, and various atomic energy raw materials.

SOURCE MATERIAL

Production and technologic data presented in this review are based primarily on information contained in quarterly and annual issues of The Australian Mineral Industry prepared and published by the Department of National Development, Bureau of Mineral Resources, Geology and Geophysics, Mineral Economics Section. The 1962 annual review and March 1964 quarterly review (vol. 16, No. 3) were the basis of the current review. Supplementary details were gleaned from many sources. These included reports of the official Australian States mining and geological agencies, various industrial and financial journals, and dispatch accounts submitted by the Minerals Officer assigned to the U.S. Embassy in Canberra.

Australia's foreign trade statistics presented herein are from the official Bulletin: Oversea Trade, Commonwealth Bureau of Census and Statistics, Canberra. Attention is drawn to the noncalendar annual fiscal period July 1 to June 30. The quantitative trade tabulations accompanying this review are from Bulletins Nos. 59 and 60, respectively, covering the 1961–62 and 1962–63 fiscal years.

PRODUCTION

In both value and volume, Australia's production of minerals in 1963 has maintained the growth trend that has been the rule throughout the past decade. The economic index of mine output, calculated at constant prices, has risen 11 percent in each of the last 2 years. Since 1951 the average annual increase was 6.9 percent.

Of more than 50 mineral commodities produced in 1963, approximately 40 recorded increases over 1962. A tenfold increase was recorded in bauxite. Other noteworthy increases were in gypsum, lead, pyrites, and titanium concentrates. Small declines were recorded in barite and in a few other nonmetallics, columbium-tantalum, and tungsten concentrates as a result of marketing or price conditions. The drop in uranium oxide output is accounted for by sales contract termination, and despite government assistance, gold mine closures continued to depress production of gold.

TABLE 1.—Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1959	1960	1961	1962	1963
Metals:					
Aluminum:					
Bauxite	15,226	70,549	16,232	30,021	355,600
Refined metal	11,552	11,842	13,416	16,460	41,925
Antimony, metal content	638	156	119	67	[1] 70
Beryl	322	193	311	227	[1] 140
Bismuth (in ore)—kilograms	420	120	410	44	----
Cadmium, refined metal—thousand kilograms	346	305	307	359	371
Chromite	122	537	----	375	----
Cobalt (recoverable cobalt in zinc concentrate)	14	13	13	16	16
Columbium and tantalum concentrate—kilograms	8,596	10,740	14,428	19,549	[1] 13,600
Copper:					
Mine (content of ore)	96,474	111,191	97,161	112,354	116,288
Blister	69,593	72,177	63,500	88,739	89,880
Refined (primary)	52,421	71,786	64,748	80,725	85,734
Gold—troy ounces	1,085,104	1,086,709	1,076,292	1,068,837	1,023,400
Iron and steel:

Fuel briquets—do	683	1,537	1,871	1,816	1,917
Petroleum refinery products:					
Gasoline—thousand 42-gallon barrels	28,262	31,963	34,347	35,089	37,872
Kerosine and jet fuels—do	2,633	3,352	3,537	3,448	3,673
Distillate fuel oils—do	15,573	19,950	19,319	19,077	20,369
Residual fuel oils—do	19,458	21,241	25,067	28,582	32,151
Lubricants—do	215	208	152	106	551
Other products—do	2,904	3,045	5,194	5,285	4,767
Refinery fuel and loss—do	6,688	6,871	6,442	8,398	9,435

[1] Estimate.
[2] Ferroalloys and steel semimanufactures are reported for fiscal years ending Nov. 30.
[3] Data not available.
[4] Petalite, amblygonite and spodumene.
[5] Includes semianthracite and subbituminous.

TRADE

According to Bureau of Mineral Resources data, the value of primary mineral exports, totaling A£94.1 million in 1962 fell short of the previous year, and was substantially lower than the record of A£113.1 million established in 1960. However, more than one-third of the 1960 record total was accounted for by gold. Exclusive of gold, the total value of exports in 1961 and again in 1962 was approximately 20 percent above the 1960 level. On the basis of calculated constant prices, the index of mineral exports has risen 56 percent in the 1959–62 period. In the overall picture, mineral exports comprise 10 percent of total exports and account for 1.3 to 1.5 percent of GNP.

758-002—65——93

Digitized by Google

Since 1960, Japan has been Australia's largest export market for minerals. In 1962, over one-fourth of the total value of exported mineral products went to Japan. The United Kingdom took about 20 percent, and the United States and Europe each took about 10 percent.

TABLE 2.—Value of metal and mineral exports

(Thousand A£)

Commodity	1960	1961	1962
Asbestos, all types	784	801	980
Coal, black	6,327	11,505	11,694
Copper:			
Ore and concentrate	8,721	6,470	4,984
Refined	4,158	6,698	4,827
Gold, metal shipments	39,280	17,265	4,932
Iron and steel:			
Pig iron	2,199	6,588	3,514
Ingots, blooms	380	3,102	3,210
Lead:			
Ore and concentrate	4,172	4,590	5,596
Pig and bullion	16,238	15,857	19,411
Manganese ore	659	690	999
Opal	1,036	1,404	2,106
Titanium concentrate	4,367	3,834	4,313
Tungsten concentrate	901	1,019	476
Uranium oxide [1]	11,300	14,000	11,900
Zinc:			
Concentrate	5,395	5,056	4,072
Slabs, blocks	3,066	4,482	7,459
Others	4,089	4,354	3,659
Total	113,072	107,715	94,132

[1] Estimate.

TABLE 3.—Exports of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1961–62	1962–63	Principal destinations, 1962–63
Metals:			
Aluminum:			
Bauxite	25	69,933	Japan 26,216; Italy 22,165.
Scrap	494	250	Japan 192.
Unwrought	72	1,871	United Kingdom 1,314; United States 519.
Semimanufactures	239	346	New Zealand 199; Hong Kong 50.
Beryllium ore and concentrate	223	118	All to United States.
Cadmium, refined metal [2]	200	260	United Kingdom 213.
Copper:			
Ore and concentrate	107,753	41,112	Japan 41,078.
Blister, cement, etc	1,038	1,347	All to Japan.
Scrap	665	354	Japan 213; Spain 56.
Ingots, blocks, billets	12,949	23,780	Japan 9,285; United Kingdom 3,665.
Semimanufactures	3,133	2,987	New Zealand 2,934.
Pipe, tubes and wire	936	2,366	New Zealand 2,287.
Gold:			
Ore and concentrate, content	troy ounces 39,835	44,166	[3].
Crude bullion, content	do 7	16,018	All to Hong Kong.
Mint bullion	do 572,052	386,768	Hong Kong 384,908.
Sheet, strip, dust	do 1,054	8,182	New Zealand 7,675.
Iron and steel:			
Iron ore and concentrate	112	115	[4].
Iron pyrites and cinder	174,415	120,236	All to Japan.
Scrap	170,693	221,665	Japan 190,746; West Germany 8,322.
Pig iron	229,270	161,918	Japan 58,355; United States 20,791.
Steel ingots, blooms, slabs, etc	161,831	55,510	United Kingdom 31,948; India 11,298.
Steel semimanufactures	479,060	256,774	Mainly to New Zealand.
Lead:			
Ore and concentrate	84,529	136,859	United States 44,823; United Kingdom 34,004.
Refined pig	203,153	171,982	United Kingdom 81,516; United States 43,268.
Bullion, lead and silver-lead	47,207	79,330	United Kingdom 60,603; West Germany 7,621.

TABLE 3.—Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1961-62	1962-63	Principal destinations, 1962-63
Metals—Continued			
Manganese ore	88,796	25,484	Japan 25,383.
Platinum-group metals:			
Ore and concentrate—kilograms	248	1,882	(4).
Platinum metals—troy ounces	383	896	United Kingdom 484; United States 412.
Silver:			
Ore, concentrate, crude bullion, content—thousand troy ounces	6,460	7,970	(2).
Mint bullion—thousand troy ounces	732	239	United Kingdom 231.
Sheet, strip, dust—do	7	4	Mainly to New Zealand.
Tantalite-columbite concentrate	17	12	United States 7; Canada 4.
Tin:			
Ore and concentrate—long tons	17	114	United States 67; Malaya 24.
Unwrought—do	1	5	(4).
Titanium concentrates:			
Ilmentite, minimum 45 percent TiO_2	151,126	146,472	United Kingdom 66,193; United States 42,210.
Rutile, TiO_2—minimum 90 percent	108,911	121,155	United States 47,258; Netherlands 11,859.
Tungsten concentrates:			
Scheelite	989	300	France 142; United States 102.
Wolframite	772	460	United States 269; United Kingdom 129.
Zinc:			
Ore and concentrate	262,657	280,735	United Kingdom 165,080; Japan 66,536.
Ingots, blocks, slabs, etc	74,323	100,315	United Kingdom 22,550; India 16,652.
Semimanufactures	1,854	788	Singapore 427; New Zealand 252.
Other forms	297	339	India 85; Other Commonwealth 101.
Zircon concentrate, minimum 30 percent $ZrSiO_4$	135,826	132,200	United Kingdom 28,886; Netherlands 23,877.
Nonmetals:			
Abrasives:			
Industrial diamond—carats	59,975	43,149	United Kingdom 39,778; Netherlands 2,389.
Other natural abrasives	37	38	New Zealand 21.
Asbestos:			
Crocidolite	8,896	5,646	United States 2,223; Singapore 1,456.
Other, amphibole and chrysotile	29	132	Singapore 45.
Cement, portland	4,511	5,480	Nauru 3,150; Christmas Island 864.
Clays, fire, sillimanite and others	655	707	New Zealand 562.
Gem stones:			
Opal—value, thousand A£5	1,691	2,347	Japan 1,831; United States 182.
Diamond—carats	9,852	1,601	United Kingdom 634; West Germany 502.
Other, cameo, talgio—value, thousand A£5	79	118	United Kingdom 77; France 14.
Graphite	3	11	(4).
Gypsum	95,517	159,902	New Zealand 78,431; Japan 43,501.
Magnesite	2,672	323	New Zealand 206; Japan 117.
Mica, crude	28	27	All to New Zealand.
Monazite concentrate	938	1,842	France 720; United States 663.
Salt	74,984	76,065	Japan 39,988; New Zealand 31,496.
Stone, construction—value, thousand A£5	4	12	(4).
Talc and steatite	5,001	3,762	New Zealand 1,131; Sweden 1,062.
Mineral fuels:			
Coal and lignite 6—thousand tons	3,525	2,719	Japan 2,511; Republic of Korea 76.
Coke	79,617	31,483	New Caledonia 22,515; Philippines 3,666.
Petroleum products:			
Gasoline—thousand 42-gallon barrels	1,416	1,302	New Zealand 1,283.
Kerosine and jet fuel—do	846	762	New Zealand 315; India 187.
Distillate fuel oil—do	4,517	5,997	New Zealand 2,417; Mozambique 649.
Residual fuel oil—do	8,383	9,459	Japan 3,460; Singapore 3,211.
Lubricants—do	43	115	Singapore 61; New Zealand 14.
Other products—do	5	143	Singapore 109; New Caledonia and Fiji 18.

[1] Periods shown are fiscal years, July 1 to June 30.
[2] Data not available on quantities of cadmium exported in lead and zinc concentrates.
[3] Destination not available. Quantities given are for 1961 and 1962 calendar years.
[4] Data not available.
[5] One Australian pound (A£1)=US$2.24.
[6] Lignite (brown coal) exports are negligible. Bulk of exports is New South Wales bituminous coal.

Digitized by Google

Aside from petroleum, Australia's balance of trade in mineral products has been highly favorable. The value of nonpetroleum mineral imports has ranged from about A£15 million to A£30 million in the past 10 years, thereby representing 20 to 30 percent of the value of exported minerals. The necessity for importing the entire national requirement of petroleum resulted in an adverse imbalance in Australia's mineral trade for most years prior to 1960. Overall favorable mineral trade balances were recorded for the first time in 1960 and 1961. The situation reversed itself in 1962, but with the planned expansion of bauxite and iron ore exports and the advent of petroleum production a favorable future appears assured.

The bulk of crude petroleum is imported from Indonesia and Middle East countries, aluminum and nonferrous metals are mostly from Canada, the United States, and the United Kingdom.

TABLE 4.—Value of metal and mineral imports

(Thousand A£)

Commodity	1960	1961	962
Aluminum, pig, ingot	6,448	3,882	7,443

COMMODITY REVIEW

METALS

Aluminum and Bauxite.—The first aluminum was produced in Australia from imported raw materials in 1955 at the 12,000-ton-per-year Bell Bay, Tasmania, plant.

Australia has one of the world's richest bauxite resources with a reserve estimated to exceed 3 billion tons. A fully integrated aluminum industry has been developed involving numerous Australian and foreign enterprises aligned for the most part in two multicompany groups. Comalco Industries Pty., Ltd. (Comalco), successor to Commonwealth Aluminum Corp., Ltd., is owned one-half by Kaiser Aluminum & Chemical Corp. (U.S.A.) and one-half by Conzinc Rio Tinto

Digitized by Google

of Australia, Ltd. Comalco owns two-thirds and the Tasmanian Government owns one-third of Comalco Aluminum (Bell Bay), Ltd., the subsidiary that operates the Bell Bay works. Comalco is also sole owner of the bauxite mines at Weipa, a principal partner in the Gladstone, Queensland, alumina project, owner of several aluminum fabricating companies, and a principal in the proposed 100,000-ton-capacity aluminum reduction plant and in the hydropower development on South Island, New Zealand.

Alcoa of Australia Pty., Ltd. was organized in June, 1961, and immediately acquired the Darling Range bauxite properties of Western Aluminum, no liability, in Western Australia. Alcoa of Australia is held 51 percent by Alcoa (U.S.A.) and 49 percent by the Australian companies: Western Mining Corp., Ltd., 20 percent; Broken Hill South, Ltd., 17 percent; and North Broken Hill, Ltd., 12 percent. The company's operating facilities include the bauxite mines, the alumina plant at Kwinana, and an aluminum smelter on Point Henry, near Geelong in Victoria. Eventual plans call for fabricating mills adjacent to the smelter.

Although bauxite had previously been produced for chemicals as well as for refractory and fluxing purposes, it was not until 1962 that Australian resources were used for aluminum reduction. The potential of extensive deposits on Gove and Cape York peninsulas, flanking the Gulf of Carpentaria on the north coast of Australia, became apparent shortly after 1950. Since 1955 exploration and development of these resources by several large Australian and foreign mining companies has been virtually continuous. In 1957 and 1958, prospecting disclosed a third vast bauxite area, in the Darling Range, near Perth in Western Australia.

Though not yet fully appraised, the deposits on Gove Peninsula, to the west of the Gulf of Carpentaria, in Northern Territory, are presumed to contain more than 100 million tons of bauxite. Concession negotiations and required development programs had not been definitely finalized at yearend. Initial testing of the Gove bauxite deposits was conducted on leases held by Comalco, Péchiney of France, Duval Holdings Pty., Ltd., and British Aluminum Company, Ltd. The British Aluminum Co.'s lease was canceled in May 1963.

The deposits of bauxite at Weipa, Queensland, developed by the Comalco organization, are estimated to contain in excess of 1 billion tons, half of which has been delimited by drilling. The grade averages 46 to 52 percent Al_2O_3. A townsite and port facilities which included the dredging of an 8-mile access channel were completed in 1962. The initial plant is designed for annual output of 400,000 metric tons. Shipments in 1963 totaled about 280,000 tons. Mining is by opencut methods. The bauxite is simply crushed and screened prior to loading for export. In addition to supplying the Bell Bay alumina plant, the company has contracted to ship 600,000 long tons of bauxite to Japan during the 3 years beginning in 1963.

The Darling Range bauxite field, near Perth, in Western Australia, extends over a belt 200 miles long by 25 miles wide. Alcoa of Australia Pty., Ltd., started production from the Jarrahdale-Dwellingup area in July 1963. This area has been estimated to contain 80 million long tons, averaging 30 to 45 percent Al_2O_3. Production of 300,000

Digitized by Google

tons was expected in 1963. The bauxite is mined by opencut, trucked about 10 miles to a crushing plant at Mundijong, and rail-shipped 17 miles to a new alumina plant at the seaport town of Kwinana, on the Freemantle harbor.

Since April 1963, the Comalco alumina plant at Bell Bay has treated Weipa bauxite exclusively. The capacity of this plant recently has been increased from 38,000 to 50,000 long tons per year. Throughout 1963 it operated at full capacity.

An alumina plant built by Alcoa of Australia Pty., Ltd. at Kwinana, 15 miles southwest of Perth, was to commerce operation early in 1964 using bauxite that had been stockpiled since July 1963 from the company's Darling Range mines. The 210,000-ton annual capacity of this plant will supply about 90,000 tons per year to the Point Henry, Victoria, smelter leaving 120,000 tons available for sale under an existing contract to Mitsubishi Chemical Industries of Japan.

Comalco Industries Pty., Ltd. and Aluminium, Ltd. of Canada in November 1963 announced affiliation with Péchiney Co. in forming a new company, Queensland Alumina, Ltd., which will build and operate an alumina plant at Gladstone, 60 miles southeast of Rockhampton, Queensland. The plant will be designed for 600,000 long tons alumina output per year, which will call for about 2 million tons of bauxite, beginning in 1967, from the Weipa mines.

Between 1961 and the close of 1963 Australia's aluminum production capacity has been raised from 16,000 to over 73,000 metric tons per year. Recent expansion and additions at Bell Bay have raised the rated capacity of that plant to approximately 53,000 tons. However, restrictions imposed by low water for hydroelectric power temporarily limited actual capacity to 40,000 tons in 1963.

The first stage of the new Alcoa of Australia Pty., Ltd. aluminum smelter at Point Henry was placed in operation and first ingots were poured on April 17, 1963. The present capacity of 20,000 tons per year will be doubled when the plant is fully completed in 1964. For the initial operation, alumina was imported from the United States. Use of domestic alumina, from the Darling Range, Western Australia, commenced in February 1964.

Cadmium.—Recorded mine production of cadmium in Australia consists of that contained in lead and zinc concentrates from Broken Hill, New South Wales, and Read-Rosebery, Tasmania. The cadmium zinc and lead-zinc ores from other Australian producers is not recorded. Accordingly, mine production of cadmium in recent years is summarized as follows:

Mine	Quantity (metric tons)			
	1960	1961	1962	1963
Broken Hill	907	858	935	1,041
Read-Rosebery	57	63	73	89
Total	964	921	1,008	1,130

Cadmium is produced as refined metal in the metallurgical plants of Broken Hill Associated Smelters Pty. Ltd. at Port Pirie; Electro-

Digitized by Google

lytic Zinc Co. of Australasia Ltd. at Risdon, Tasmania; and Sulphide Corporation Pty. Ltd. at Cockle Creek, New South Wales. Production by these plants was:

Plant	Quantity (metric tons)	
	1961	1962
Port Pirie	64	16
Risdon	243	266
Cockle Creek	9	77
Total	316	359

Consumption of refined cadmium by Australian industries, for plating, manufacture of alloys, chemicals and pigments has totaled up to 187 metric tons annually. In addition to the recorded exports of refined metal a substantial quantity of cadmium is contained in base metal concentrates that are shipped abroad for treatment. Lead-zinc concentrates exported in 1962 from New South Wales contained 442 metric tons of cadmium. Similar data for other States are not available.

Copper.—Although Australia's mine copper production constituted only about 2.5 percent of the 1963 world supply, it has been that country's principal metallic mineral from a value viewpoint. In 1962 copper in ore and concentrate was valued at A£24.7 million, to which A£5.6 million was added by reason of primary treatment. In 1962 and again in 1963 mine output and production of blister and refined copper were at record levels. Over 90 percent of the national production was by four companies; however, eight important mines, four smelters, and three refineries comprise the copper industry.

TABLE 6.—Major copper industry facilities by area

Area and facility	Production (metric tons of copper [1])	
	1961	1962
Mines:		
Queensland:		
Mt. Isa Mines Ltd	58,644	75,975

Refineries, electrolytic:		
Queensland: Mt. Isa Mines Ltd.—Townsville	41,255	57,664
New South Wales: Electrolytic—Port Kembla	12,875	11,156
Tasmania: Mt. Lyell Mining and Railway Co. Ltd	10,618	11,905

[1] Metal content of ore for mines; blister copper for smelters; and refined copper for refineries.

Digitized by Google

In addition to the copper reported as mine production in 1963, Mt. Isa Mines Ltd. accumulated 10,000 metric tons of copper in oxide ore from the new open pit development. The oxide orebody has been outlined by diamond drilling. Production from this work is expected to provide a substantial increase in Mt. Isa output beginning in 1965 or 1966. Total Mt. Isa ore reserves as of June 30, 1962, were estimated at 27 million tons: 1.5 million of oxide ore averaging 4.2 percent copper and 25.5 million of sulfide ores averaging 3.6 percent copper. Because of the closing of the Captains Flat and Rum Jungle mines, the supply of concentrate to the Electrolytic Refining and Smelting Co. customs smelter at Port Kembla has decreased in recent years. This shortage will be relieved beginning in 1966 when annual shipments of about 80,000 tons of concentrate are expected from Cobar.

Mineable reserves at Cobar, New South Wales, are reported to total 18 million tons of ore averaging 3.54 percent copper. The mine is being developed for underground operation, employing mechanical cut-and-fill methods by Cobar Mines Pty. Ltd., which is owned jointly by Broken Hill South Ltd. (77 percent) and Conzinc Rio Tinto of Australia Ltd. (23 percent).

Gold.—In 1962, 14 principal producers of gold are listed by the Bureau of Mineral Resources;[3] however, the total number, including very small operations, may approximate 295 as reported officially in 1961. Total mine output of gold has decreased an average of about 1 percent per year since 1959. The current annual production level is approximately half the peak of 2,065,000 ounces recorded in 1903. Historically, nearly two-thirds of Australia's total gold production through 1962, estimated at 182 million ounces, was from the eastern States of Queensland, New South Wales, and Victoria, with Victoria alone accounting for 41 percent of the historical total. In recent years, however, Western Australia's mines have yielded over 80 percent of the national output of gold. In 1962 and 1963 mine production was from the following regions:

Area	Quantity (thousand troy ounces)		Area	Quantity (thousand troy ounces)	
	1962	1963		1962	1963
New South Wales	11.2	11.6	Western Australia	860.0	802.9
Victoria	28.3	24.7	Tasmania	32.1	36.2
Queensland	67.7	67.5	Northern Territory	69.4	79.7

[3] Department of National Development, Bureau of Mineral Resources, Geology and Geophysics (Canberra). The Australian Mineral Industry, 1962 Review. 1963, 316 pp.

Digitized by Google

Principal company sources, all in Western Australia, were as follows in 1962:

Company	Location	Ore treated 1962 (long tons)	Gold produced 1962 (troy ounces)
Central Norseman Gold Coporation N.L.	Norseman	181,834	109,506
Gold Mines of Kalgoorlie (Australia) Ltd.	Fimiston and Coolgardie	514,594	139,649
Great Boulder Gold Mines Ltd	Fimiston	455,399	121,799
Great Western Consolidated N.L	Bullfinch, Southern Cross, Nevoria	390,462	61,352
Hill 50 Gold Mine N.L	Mt. Magnet	165,698	87,196
Lake View and Star Ltd	Fimiston	694,054	181,195
North Kalgurli (1912) Ltd	do	368,350	84,559

The bulk of Australia's gold, virtually all from Western Australia and from the several small mines that contribute to the Victoria production, was recovered by amalgamation and cyanide treatment of gold ores. The production credited to Tasmania is largely from auriferous lead-copper concentrates. The bulk of Queensland's gold is from the Mt. Morgan copper-gold ore; New South Wales' gold is associated with lead and zinc concentrates from Broken Hill. In 1962 and 1963 national production contained in the mine or mill products included:

Type of mine or mill product	Quantity (troy ounces)		Type of mine or mill product	Quantity (troy ounces)	
	1962	1963		1962	1963
Copper concentrate	78,581	90,899	Lead concentrate	12,286	13,814
Copper ore	223	134	Lead-copper concentrate	18,021	18,820
Bullion [1]	955,285	894,424	Zinc concentrate	4,441	4,486

[1] Includes alluvial and retorted gold.

Three gold mines, two in Western Australia and one in Victoria, were closed during 1963. A development program at Mt. Charlotte, near Fimiston, Western Australia, by Gold Mines of Kalgoorlie (Australia) Ltd. is expected to add an output of 20,000 ounces per year when production commences in 1964.

Payments of subsidy under the Gold Mining Industry Assistance Act total A£748,509 in 1962. The act was extended for 3 years, to May 1965.

The new Gold Mines Development Assistance Act of 1962, assented to on December 14, 1962, is designed to stimulate mine development in mines that do not receive subsidy.

Iron and Steel.—In 1963, production records were established in Australia for iron ore, pig iron, and steel. The strong domestic demand for iron and steel products and the added output of new steelmaking facilities that came into use late in 1962 and early in 1963 at Newcastle, New South Wales, were the principal contributing factors. The testing and development of recently discovered iron ore deposits continued throughout the year, particularly in Western Australia.

Digitized by Google

Iron Ore.—Production of iron ore in 1963, as in previous years, was almost entirely from the Broken Hill Pty. Co. Ltd. (BHP) mines on the Middleback Range, near Whyalla in South Australia, and from Cockatoo Island, Yampi Sound in Western Australia. The State of Western Australia owns and operates a small iron mine at Koolyanobbing (200 miles east of Wundowie) that supplies the Charcoal Iron and Steel Industry works at Wundowie. By regions, quantities of iron ore mined for iron and steel making, during 1961 and 1962 were as follows:

Area	Quantity (thousand metric tons)		Area	Quantity (thousand metric tons)	
	1961	1962		1961	1962
South Australia: Middleback Range	4,046	3,495	Western Australia: Cockatoo Island, Yampi Sound	1,305	1,342
			Koolyanobbing	76	85

A scree [4] ore treatment plant of 800,000 tons per year capacity was placed in operation at Iron Knob in the Middleback Range in August 1962. The bulk of the ore produced in the range is high-grade hematite, 65 to 68 percent iron, mined by opencut methods. It is shipped 30 to 40 miles by rail to Whyalla and thence by sea to Newcastle and Port Kembla. Ore reserves in 1960 were estimated at 200 million metric tons of hematite carrying 65 percent iron and 5 billion tons of hematite-jaspilite ore with up to 40 percent iron.

The Yampi Sound hematite deposits on Cockatoo and Koolan Islands were estimated in 1957 at 70 million tons, above water, averaging about 64 percent iron. The hematite-limonite orebody at Koolyanobbing was recently estimated to contain 70 million tons, carrying from 50 to 63 percent iron.

Under the liberalized iron ore export policy announced by the Commonwealth Government in December 1960, and further relaxed in June 1963, exploration as well as geological and economic developments have moved forward at a very rapid rate. In November 1962, reserves of iron ore in the newly investigated areas of Western Australia were estimated to total about 8 billion tons. Most of the reserve is in the Hammersley and Ophthalmia Ranges of the Pilbara District. More than 100 temporary exploration concessions for iron ore were granted by the Western Australian Government in 1962 to various interests. Six approvals have been granted by the Commonwealth Government for export of various quantities of iron ore; the largest contract for 200 million tons to be delivered during a period of 21 years. Several negotiations being considered early in 1964 involved an additional quantity of more than 300 million tons.

Exploration and testing of the Savage River area in northwest Tasmania has been by the Bureau of Mineral Resources, Geology and Geophysics, and the Tasmanian Mines Department. Mining rights are currently held by private industrial interests. Preliminary studies

[4] Scree—talus, in this locality low-grade, siliceous, hematite-jaspilite type ore.

Digitized by Google

indicate a possible 200 million tons of magnetite ore containing about 45 percent iron and 1.7 percent titania.

A comprehensive status résumé of recent Australian iron ore prospecting and development activities in addition to commercial negotiations was published early in 1964.[5]

Pig Iron.—The blast furnaces of Broken Hill Pty. Ltd. and its subsidiary companies [6] account for all of the pig iron produced in Australia with the exception of about 50,000 tons of charcoal pig produced annually by the Wood-Distillation, Charcoal-Iron & Steel Industry at Wundowie, Western Australia, which is State-owned. Pig and foundry iron output in 1961 and 1962 was by the following producers:

Company	Location	Quantity (thousand metric tons)	
		1961	1962
Broken Hill Pty. Ltd	Newcastle	939	997
Do	Whyalla	251	220
Do	Port Kembla	1,949	2,226
Wood-Distillation, Charcoal-Iron & Steel Industry	Wundowie	52	47

The outstanding development in 1963 was commissioning of the new No. 4 blast furnace at the Newcastle plant in July. As a result of this increase, national pig iron production capacity has been raised to approximately 4 million metric tons per year.

Steel and Steel Products.—By the close of 1963, steelmaking capacity in Australia was approximately 5 million metric tons per year. All but a few thousand tons of this was the product of Broken Hill Pty. Co. Ltd. and its wholly owned subsidiaries; Australian Iron and Steel Pty. Ltd.; and Commonwealth Steel Co. Ltd. Production of various items during the company's annual fiscal periods ending May 31, 1962, and May 31, 1963, were reported as follows:

Commodity	Quantity (thousand metric tons)		Commodity	Quantity (thousand metric tons)	
	1962	1963		1962	1963
Steel ingots	4,127	4,325	Rod	147	153
Blooms and slabs	3,471	3,772	Cold rolled strip	32	60
Sheet bars, billets, etc	1,976	1,997	Tinplate	108	214
Plate and strip	1,119	1,458	Steel castings	10	10
Merchant	1,257	1,310	Spun pipes	64	36

Capital expenditures by the BHP Company in its industrywide expansion and modernization program has exceeded A£125,000 during the past 3 years. At Newcastle, major units associated with the basic oxygen steelmaking processes have been completed. The first and second basic oxygen furnaces, including the electrostatic precipitators,

[5] Ives, D. J., Development Toward Exports of Australian Iron Ore. The Australian Mineral Industry, Canberra, Australia, v. 16. No. 3, March 1964, pp. 65–71.
[6] Subsidiaries include Commonwealth Steel Co. Ltd., plants at Waratah and Wollongong, New South Wales, and Australian Iron and Steel Pty. Ltd. plants at Port Kembla, New South Wales.

Digitized by Google

were put into service; one bloom mill, two improved continuous mills, and one new rod mill were commissioned during the period from October 1962 to February 1963. Principal installations completed at Port Kembla during 1962–63 included an oxygen plant, a central laboratory, and a narrow cold-rolled products plant. Construction is currently proceeding on additional soaking pits and on a 140-inch plate mill at Port Kembla as well as on an extensive additional steelmaking facility at Whyalla.

Lead and Zinc.—Since 1957 when Australia's output of lead surpassed that of the United States, Australia has been the free world's leading producer of lead. In zinc, Australia ranks third after the United States and Canada. Throughout 1963 production of lead and zinc was at full scale, with the result that records were established for mine output of both metals. Between June 1959 and March 1962 voluntary curtailment had been applied by the industry in cooperation with International Lead Zinc Study Group schedules.

The zinc and nearly all of the lead produced in Australia is mined in lead-zinc multimetal ore containing varying quantities of gold, silver copper, cadmium, manganese, and other elements. Virtually all production has been from the four localities of Broken Hill and Captain's Flat, New South Wales; Mt. Isa, Queensland; and Reed-Rosebery, Tasmania. The principal mine sources for 1961 and 1962 production were as follows:

Mine	Quantity (metric tons)			
	1961		1962	
	Lead	Zinc	Lead	Zinc
North Broken Hill	49,393	39,984	57,556	47,235
Broken Hill South	31,476	27,350	36,704	31,168
Zinc Corporation	70,067	71,078	108,285	81,093
New Broken Hill Consolidated	54,809	85,995	92,830	86,303
Captain's Flat	9,125	17,087	1,646	2,993
Mt. Isa	45,727	33,752	63,648	45,421
Reed-Rosebery	11,859	40,750	14,365	48,657

The lead-zinc industry comprises a total of about 25 mines, which in 1963 shipped 12,200 metric tons of ores, 603,113 tons of lead and lead-copper concentrates, and 605,641 tons of zinc concentrates. Because of the exhaustion of reserves, Lake George Mines Pty. Ltd. at Captain's Flat and Barrier Central Pty. Ltd. at Broken Hill ceased operations in 1962.

All Mt. Isa lead concentrates are smelted in the company's lead smelter, the metal being exported to the United Kindom for refining. Except for a very small quantity of zinc concentrate which has been shipped in some years to Risdon, Tasmania, the bulk of Mt. Isa zinc concentrate is exported.

The new lead-zinc smelter complex at Cockle Creek operated by Sulphide Corporation Pty. Ltd.[7] is entirely supplied by Broken Hill. Its rated capacity is 40,000 long tons each metal per year, and products

[7] Mining World. V. 25, No. 1, January 1963, pp. 16–19.

Digitized by Google

are all exported. The great bulk of the Broken Hill concentrates are processed in the Broken Hill Associated Smelters Pty. Ltd. 200,000 ton-per-year capacity lead smelter at Port Pirie, New South Wales, and in the 120,000-ton-per-year Electrolytic Zinc Company of Australasia Ltd. plant at Risdon, Tasmania.

Manganese Ore.—Reflecting world market conditions, in 1963 Australian production of manganese ore declined to approximately half of the 1962 level. Decreased demand for Australian metallurgical grade ore by the Japanese steel industry was a major influence.

The domestic pattern of manganese consumption has been altered by the commissioning of the new ferroalloy plant of Tasmanian Electrometallurgical Co. Pty. Ltd. at Bell Bay, Tasmania. Consumption of metallurgical grade ore in Australia in 1962 was estimated at 45,000 metric tons, of which a third was from domestic sources. Imports of ferromanganese fell in 1962 to 8,863 tons, compared with an average of nearly 36,000 tons in the previous 2 years.

Silver.—The successive 1962 and 1963 records for silver production in Australia reflect the high level of lead-zinc production in the Broken Hill area of New South Wales, Mt. Isa, Queensland, and Reed-Rosebery, Tasmania. In 1961 and 1962, these areas accounted for 94.6 and 96.7 percent, respectively, of the total Australian silver production. In both years, more than half of the total was from Broken Hill. Since 1960 all silver mined in Australia has been associated with ores of other metals; the mine products of 1962, for example, contained the following quantities of silver:

Mine product:	*Silver content (troy ounces)*
Copper ore	12,369
Copper concentrate	831,561
Gold, bullion, retorted, etc	225,323
Lead ores	40,037
Lead concentrate	14,751,653
Lead-copper concentrate	994,880
Zinc concentrate	697,868

Most of the silver refined in Australia is recovered from lead concentrate smelted by Broken Hill Associated Smelters Pty. Ltd. at Port Pirie, South Australia. Smaller quantities are also refined by Electrolytic Refining and Smelting Company of Australia Pty. Ltd. at Port Kembla, New South Wales, and by the Royal Mint facilities in Melbourne and Perth.

Domestic sales normally absorb less than half of the national output. Exports of silver in unrefined bullion, concentrates and other raw products have ranged from 6.4 to more than 8.0 million ounces annually in recent years. Refined silver exports have been relatively small, with much variation in quantity.

Tin.—With the addition of new production from the opencut operation at Ardlethan, New South Wales, and increases from the Pilbara field in Western Australia and Finches area in northern Queensland, mine production of tin in 1963 was the highest in recent decades but is far short of the 8,000- to 10,000-ton annual peaks of the 1870–90 period. Total Australian production of tin metal to date (1963) has been estimated at 465,000 long tons. Production has been reported from all Australian states except South Australia. More than 200

Digitized by Google

mines normally contribute to the total tin production from various types of mine workings. Sluicing and dredges are used on surface alluvial deposits; underground methods are used on numerous lode occurrences.

The various States as well as the Commonwealth Government encourage and assist in the exploration and development of tin prospects. The Ardlethan development was largely the result of drilling, a type of assistance rendered by the New South Wales Mines Department, and the result of metallurgical research conducted in Commonwealth and Tasmania Mines Department laboratories. In mid–1962 the Northern Territory Administration opened a government mill at Mt. Wells to treat tin ore produced by small operators.

Four companies, two in Queensland and two in Tasmania, account for more than half of the national total. Principal producers of tin in 1962 were as follows:

Area and Company:	*Concentrates (long tons)*
Queensland:	
Ravenshoe Tin Dredging Ltd	568
Tableland Tin N.L	397
Tasmania:	
Aberfoyle Tin N.L	777
Renison Associated Tin Mines N.L	362
Storey's Creek Tin Mining Co. N.L	123
Endurance Tin Mining Co. N.L	51
Western Australia:	
Mineral Concentrates Pty. Ltd	121
Northern Minerals Syndicate	72
J. A. Johnson	111
H. V. Leonard	99

Virtually all domestic tin is smelted and refined in Sydney, New South Wales, by either O. T. Lempriere and Co. Ltd. or by the Sydney Smelting Co. Pty. Ltd.[8] The rated capacities of these two tin smelters are 2,500 and 1,500 long tons per year respectively.

Titanium Concentrates.—Australia in 1962 accounted for 8.9 percent of the ilmenite and 88.3 percent of the rutile produced in the free world.

Production of ilmenite concentrate from beach sands has increased at a phenomenal rate since 1954, the initial year of recorded Australian production. With the exception of a few thousand tons from east coast beaches, the ilmenite industry is dominated by four companies situated 100 to 125 miles south of Perth, Western Australia: Western Titanium, N.L., and Western Mineral Sands Pty. Ltd. at Capel, Westralian Oil Ltd. at Yoganup, and Cable (1956) Limited at Bunbury.

In addition to ilmenite, the beach sand resources yield other products as illustrated by Westralian Oil Ltd., which in 1963 reported production of 75,000 metric tons ilmenite, 9,214 tons zircon, 1,300 tons monazite, and 6,440 tons leucoxene.

Ilmenite concentrate output from Western Australia is expected to more than double because of expansion of existing facilities and the added production from a new 100,000-ton capacity plant of Western Mineral Sands Pty. Ltd. that will be put into operation early in 1964.

In 1963 rutile production, nearly all from New South Wales and

[8] Subsidiary of Consolidated Tin Smelters Ltd.

Digitized by Google

Queensland, was 40 percent above the previous record of 131,000 metric tons in 1957. The principal stimulant has been contract purchases totaling more than 80,000 tons annually by U.S. pigment manufacturers including E. I. du Pont de Nemours & Co., Inc., American Potash & Chemical Corp., Godfrey Cabot Corp., and American Cyanamid Co.

The east coast beach sands industry that numbered about 30 separate companies during 1956–58 has emerged in 1961–63 with Consolidated Gold Fields (Aust.) Pty. Ltd. in control of more than half the east coast production capacity. The Du Pont contract which currently amounts to 50,000 long tons per year is with Rutile and Zircon Mines (Newcastle) Ltd. Smaller scale producers include the long-established N.S.W. Rutile Mining Company Pty. Ltd. and Cudgen R. Z. The principal centers of production are the coastal regions adjacent to Newcastle, New South Wales, and Brisbane, Queensland.

Uranium Oxide.—Since 1944 a large number of uranium occurrences have been reported in Australia but only five were developed and brought to production. Of these, the South Alligator Uranium N.L. mine in Northern Territory and the Radium Hill Mine, South Australia, suspended operations in 1961 and 1962, respectively, because ore reserves of both companies were exhausted. Mary Kathleen Uranium Ltd., the largest Australian producer, completed its 9-million-pound contract with United Kingdom Atomic Energy Authority and closed in November after producing 728 metric tons U_3O_8 in 1963, a decrease compared with 907 metric tons produced during the previous year.

The United Uranium N.L. at Moline, Northern Territory, has continued operation to satisfy a A£5 million contract with the United Kingdom Atomic Energy Authority. Completion of this contract is scheduled for July 1964. The Rum Jungle operation of Territory Enterprises Pty. Ltd. will continue to treat stockpiled ore from the Rum Jungle Creek South opencut. Products will be stockpiled pending development of a favorable market. At the present treatment rate—274 metric tons U_3O_8 in 1963—the stockpile operation will continue until about 1971.

Total Australian production of uranium oxide when all contracts are complete will total about 9,000 metric tons. Known reserves according to a 1964 estimate are 8,000 tons, of which about 1,800 tons are at Rum Jungle and 6,200 tons at the Mary Kathleen mine.

Zircon.—While output data for zirconium concentrate are not available for many producer countries, Australia is the uncontested leading producer in the free world, accounting for about 60 percent of the supply. In 1963 output of zirconium concentrate was at a record high, reflecting increases in production of ilmenite and rutile beach sands from which the zirconium concentrate is recovered. Virtually all zirconium concentrate is exported. U.S. imports increased to over 55,000 metric tons in 1963; this is more than double the quantity imported in 1962.

NONMETALS

Asbestos.—The bulk of Australia's asbestos production is of crocidolite (blue) variety, mined at Wittenoom Gorge, Western Australia, by Australian Blue Asbestos Pty. Ltd. In 1962 this company milled

Digitized by Google

304,073 metric tons of ore, yielding 15,867 tons of marketable product. However, reflecting a highly competitive market, exports including completion of a U.S. stockpile contract for 4,536 tons (5,000 short tons), fell to 8,800 tons in 1962 and to less than 3,000 in 1963.

Chrysotile asbestos was produced in 1963 by Asbestos Mines Pty. Ltd. at Baryulgil, New South Wales, and by L. G. Hancock at Lionel, Western Australia. However, this output, amounting to less than 1,000 tons annually since 1958, continued to decline in 1962 and 1963.

With the nationwide expansion in construction activity, asbestos consumption, supplied by imports mainly in raw form from Canada, has risen from about 26,000 tons in 1952 to 43,000 tons in 1963. Although statistics of consumption of asbestos byproducts are not published, consumption of Australian-made asbestos cement products, chiefly wallboard, was 41,354 metric tons in 1960–61 and 35,408 tons in 1961–62.

Gem Stones.—Opal and sapphire are produced in small commercial quantities in Australia. Production of opal, most of which came from Coober Pedy, Andamooka, and Mintabee fields in South Australia, was valued at record A£1.14 million in 1963. Smaller amounts have been produced in past years in Queensland and New South Wales. In 1962 opal mining activities at Lightening Ridge in New South Wales occupied 200 men and production was valued at A£100,000. The A£2.7 million value of opal exported in 1963 was also a record. Export value includes the benefit of cutting, trimming, or otherwise processing the run-of-mine products.

The sapphire produced in New South Wales and Queensland in 1962 was valued at A£35,819. The principal producers were Sapphires Pty. Ltd. and Gaukroger, Dawes, and Williams in the Glenn Innes and Inverell mining divisions in New South Wales. The Anakie district in central Queensland accounted for most of the A£4,690 value of sapphire credited to Queensland in 1962.

Gypsum.—Production of gypsum has grown steadily for the past 10 years. The 1963 record output was 10 percent higher than in 1962, and in both years approximately 20 percent of the total production was exported. The Bureau of Mineral Resources lists 23 companies engaged in producing gypsum in South Australia, Victoria, New South Wales, and Western Australia. Two-thirds of the total is normally produced in South Australia.

The bulk of production is controlled by two companies that also manufacture and market gypsum products. Australian Gypsum Industries Ltd. (A.G.I.) accounts for over half of the total annual production. Its mining subsidiaries are located at Kowulka and Stenhouse Bay, South Australia; Ivanhoe, New South Wales; and at Yaapeet, Victoria. The Colonial Sugar Refining Co. Ltd. (C.S.R.) produces nearly one-third of the total from subsidiary mines on Kangaroo Island and at Lake MacDonnell in South Australia; at Conoble and Manara, New South Wales; Nowingi, Victoria, and at Yellowdine in Western Australia.

Apparent consumption of gypsum in 1963 was on the order of 555,000 metric tons, compared with about 500,000 tons in 1962. The largest industrial usage in 1963 was for plaster of paris—252,000 tons—and portland cement—about 150,000 tons. Details are not avail-

Digitized by Google

able on the large quantities consumed in manufacture of plaster sheets, acoustic tiles and other construction materials.

Monazite.—Australia is one of the world's leading producers of monazite. Official statistics report sales or shipments rather than actual production; accordingly, although for both 1962 and 1963 output records were established, 1963 is credited with an outstanding 2,096 tons of concentrate containing 1,973 tons of monazite. The concentrates are recovered as a byproduct of beach sands operations. The largest production, about 70 percent of the total, is from ilmenite beach sands in Western Australia. Smaller quantities are byproducts of rutile and zircon sands from Queensland and New South Wales.

The recent increase in monazite production reflects the high level of activity in Australian ilmenite and rutile beach sands. The additional new recovery plants for titanium minerals, which were completed in 1962 and 1963, are expected to yield still greater quantities of byproduct monazite in 1964 and 1965. The entire output of monazite concentrate is exported.

Phosphate Fertilizers.—Australian production of phosphate is insignificant in the national requirement picture. Production from South Australia has accounted for about 5,000 metric tons annually in 1961, 1962, and 1963, and in some years a few tons have also been reported from Western Australia.

Interest has been stimulated with two recent discoveries of phosphate rock in Northern Territory. The first discovery, in 1961, was in the Castlemaine Hill and Stapleton areas near Rum Jungle. Reports of preliminary tests by the Bureau of Mineral Resources have shown that this phosphate bed, considered unsuitable for production of superphosphate, extends to a depth of 200 feet and averages about 12 percent P_2O_5. The second discovery was in the Amadeus Basin, west of Alice Springs, in 1962, where the phosphate occurs in thin beds which yield analyses up to 22 percent P_2O_5.

Production of superphosphate fertilizer, based on rock imports from Christmas, Nauru, and Ocean Islands was a record 3,142,000 metric tons in 1963, compared with 2,823,000 in 1962. In addition to general economic prosperity, the expansion is largely the result of the superphosphate bounty of A£3 per ton to the consumer which was initiated by the Commonwealth Government in mid-1963.

Sulfur.—Occurrences of native sulfur are unknown in Australia. Nearly all requirements of elemental sulfur, which exceeded 225,000 tons annually in 1962 and 1963, were imported from the United States, Mexico, and Canada. Sulfur recovery plants at two oil refineries, the 40-ton-per-day plant at Altona, Victoria, and the 30-ton plant at Port Stanvac, South Australia, both owned by Petroleum Refineries (Australia) Pty. Ltd., have been producing since 1960 and May 1963, respectively.

Under the Sulphuric Acid Bounty Act of 1960, A£3 per ton has been paid by the Commonwealth on acid produced from indigenous pyrites; and since a 1963 amendment to this Act, A£1 2s per ton is now payable on sulfur in gas from sintering lead concentrate.

Pyrite is mined as a source of sulfur by Nairne Pyrites Ltd. at Nairne, South Australia, and by Norseman Gold Mines, N.L., at Norseman, Western Australia. It is also recovered commercially as a

Digitized by Google

byproduct of base metal ore milling at Mt. Morgan, Queensland, Mt. Lyell, Tasmania, and from gold ores at Kalgoorlie, Western Australia. Total production of pyrite concentrates from these sources in 1962 amounted to 150,950 metric tons with a sulfur content of 66,107 tons.

Most of the recoverable sulfur contained in indigenous pyrite and other sulfide materials as well as most of the imported elemental sulfur goes into the manufacture of sulfuric acid. About 12,000 tons of elemental sulfur were used for nonacid purposes, whereas more than 200,000 tons went into the manufacture of sulfuric acid. The source materials used and quantities of sulfuric acid produced from each in 1962 were in thousand metric tons:

Source material	Amount used	Acid produced	Source material	Amount used	Acid produced
Elemental sulfur	217	630	Lead concentrate	292	63
Pyrite	239	304	Other materials	35	49
Zinc concentrate	235	203	Total		1,249

Production of sulfuric acid, stimulated by the heavy demand for manufacture of superphosphate, rose to a record of 1,336,700 metric tons in 1963, compared with 1,249,000 tons in 1962. Consumption of acid in 1963 totaled 1,332,000 tons. Approximately 80 percent of this was for superphosphate.

Salt.—Favorable marketing conditions for Australian salt spurred production to records in all five producing States in 1962 (data for 1963 are not available). National output in 1962 was 5 percent above the previous year's total. All production is from solar evaporation pans and dry lakes. In 1962, approximately 83 percent of the total production was from solar evaporation of sea water. The Bureau of Mineral Resources lists 18 producing companies. Among the largest saltworks are: I.C.I. Alkali (Australia) Pty. Ltd. at Dry Creek, South Australia; Broken Hill Proprietary Co. Ltd. at Whyalla, South Australia; Central Queensland Salt Industries Ltd. near Port Alma, Queensland; Cheetham Salt Ltd. at Laverton, Lara and Geelong in Victoria; and Garrick Agnew Pty. Ltd. near Port Gregory, Western Australia. The State of South Australia usually accounts for more than two-thirds of the national production. In 1962 South Australia produced 396,000 tons of salt.

No details concerning consumption of salt are available. Official estimates of apparent consumption for the 3 years 1960–62 were 471,900, 468,300 and 475,700 tons, respectively. Recorded consumption in metric tons by the two principal industries for recent fiscal years (July 1 to June 30) are given:

	1959–60	*1960–61*
Industrial chemicals	278,157	272,676
Salt refining	149,569	162,961

MINERAL FUELS

The role of mineral fuels in the national energy pattern of Australia is summarized in annual reports of the Joint Coal Board. For recent fiscal periods, July 1 to June 30, consumption of energy from various sources and percentage of total has been as follows:

Digitized by Google

	1960–61		1961–62		1962–63	
	Thousand metric tons SCE [1]	Percent	Thousand metric tons SCE [1]	Percent	Thousand metric tons SCE [1]	Percent
Black coal	19,063	42.7	18,909	41.3	18,948	39.3
Lignite	5,453	12.2	5,851	12.8	6,114	12.7
Petroleum products	16,914	37.9	17,689	38.7	19,142	39.7
Firewood	1,030	2.3	977	2.1	894	1.9

Total	44,633	100.0	45,738	100.0	48,208	100.0

[1] Standard coal equivalent.

Coal.—*Black Coal.*[9]—For the fourth successive year, Australian production of black coal established a new record in 1963. While the bulk of the output, as usual, was from New South Wales, increases in South Australia and Queensland were primarily responsible for the national total passing the 25-million-ton milestone.

TABLE 7.—Black coal production distributed by type and State

(Thousand metric tons)

State	Bituminous			Subbituminous			Semianthracite		
	1961	1962	1963	1961	1962	1963	1961	1962	1963
New South Wales	19,326	19,335	19,245						
Queensland	2,693	2,691	3,126	76	84	110	58	69	60
South Australia				1,133	1,414	1,536			
Tasmania	258	275	208				2	2	3
Victoria	67	58	52						
Western Australia				778	934	915			
Total	22,344	22,359	22,631	1,987	2,432	2,561	60	71	63

According to 1962 lists published by the Bureau of Mineral Resources, there were 19 companies in Queensland, each producing more than 50,000 tons per year; 10 companies in New South Wales, each producing more than 400,000 tons per year; 6 companies in Tasmania, 2 companies in Western Australia, and 1 company each in South Australia and Victoria. The total tonnage of coal mined by opencut methods was 3.2 million tons in 1962, compared with 2.9 million in 1961. Productivity in the principal producing States for these 2 years was:

State	Production per man-shift [1] (Long tons)			
	Underground mines		Opencut mines	
	1961	1962	1961	1962
New South Wales	6.23	6.57	22.99	22.42
Queensland	3.46	3.57	11.43	10.42
South Australia			14.91	19.78
Western Australia	4.0	4.35	9.63	10.32

[1] On the basis of all employees.

[9] Includes bituminous, semianthracite, and subbituminous varieties.

Digitized by Google

Estimates of Australian black coal reserves summarized in the Report of the Coal Utilization Research Advisory Committee, published by Bureau of Mineral Resources in 1962, were:

State	Quantity (million long tons)		State	Quantity (million long tons)	
	Measured and indicated	Inferred		Measured and indicated	Inferred
New South Wales	3,050	10,000+	Victoria	20	10
Queensland	950	10,000+	Western Australia	274	1,600
South Australia	130				
Tasmania	Small	137	Total	4,424	22,000+

Domestic consumption of black coal has increased only slightly in the past 4 years. Distribution of black coal consumed in the 1961–62 and 1962–63 fiscal years was:

Consumer	Consumption (thousand metric tons)		Consumer	Consumption (thousand metric tons)	
	1961–62	1962–63		1961–62	1962–63
Iron and steel	5,221	5,259	Ships bunkers	128	119
Electricity	7,609	7,935	Other	2,699	2,684
Railways	1,680	1,567			
Town gas	1,626	1,486	Total domestic consumption	20,138	20,260
Cement	869	867			
Metallurgical coke	306	343			

Exports of black coal in 1963 were about 3.2 million tons of which 2.7 million was from New South Wales, largely from the Southern field. A number of new contracts to supply coking coal were recently negotiated with Japan. The contracts, which involve four companies, call for a total of more than 1 million tons annually for 3 years to be supplied from the South Coast area of New South Wales. The announced estimates of Japanese total requirements for 10 million metric tons of coking coal in the financial year beginning April 1, 1964, anticipate 3.9 million tons from Australia. Filling this order should raise Australian coal exports to new records in 1964.

Early in 1964 the Queensland Government announced that investigating companies had established reserves of 1 billion tons of coking and steaming coal in the Blackwater-Nebo coalfield of Central Queensland.

Coke.—Production of metallurgical coke was at a record level of 2.9 million metric tons in 1963, thus continuing the increase that throughout recent years has been the trend of iron and steel. According to 1962–63 data, 26 percent of all black coal produced in Australia has been used by the iron and steel industry, mainly for production of metallurgical coke. A relatively small quantity of coal, 343,000 tons in 1962–63, is used to make metallurgical coke for iron foundries, nonferrous metal smelters and other consumers.

Digitized by Google

The steel industry's coke making installation include the Port Kembla works of Australian Iron and Steel Co. Ltd. rated at 2.5 million metric tons carbonizing capacity and the Broken Hill Proprietary plant at Newcastle rated 1.7 million tons. In 1962 these plants produced 1,817,000 and 1,047,000 metric tons of coke, respectively. Byproducts included tar, motor benzol, toluol, naphtha, ammonium sulphate, ammonia, and pyridine. In contrast to previous years when up to 100,000 tons of Australian-made coke was available for export in 1963 all but about 30,000 tons was used domestically.

Metallurgical coke for industries other than steel was made in beehive ovens by four companies in the Southern coalfield and ore in the Northern coalfield of New South Wales. In Queensland, beehive coke oven plants are operated by the State Coalworks at Bowen and Haighmoor. The Queensland plants produced 11,000 metric tons in 1961, and 17,270 in 1962.

Consumption of beehive metallurgical coke by Australia's nonferrous smelters has been estimated by the Coal Utilization Research Advisory Committee 118,000 metric tons in 1962 and 131,000 tons in 1963. The iron foundry industry, numbering 400-odd establishments normally used over 100,000 tons per year.

Brown Coal.—Production and consumption of brown coal (lignite) in Australia are approximately equal, since none is exported. The only production is from southern Victoria, although small deposits are also found in South Australia. The value of brown coal produced in 1962 represented 80 percent of the total mineral production of the State of Victoria. The State Electricity Commission, operating open pits at Yallourn and Morwell in the Latrobe Valley, accounted in 1962 for 96.5 percent of the national production. Four private companies supplied the balance. To accommodate the expanding demand primarily for generation of electrical energy in Victoria, production of lignite has increased at an average rate of nearly 10 percent per year throughout the last decade. Completion of the Hazelwood power station, the first third of which is scheduled to begin in 1965, will call for an additional 13 million tons by 1971.

Reserves of brown coal, according to estimates in 1962 by the Coal Utilization Research Advisory Committee are impressive: 54.7 billion long tons measured and indicated, and 43.0 billion inferred.

While the great bulk of these reserves are in Victoria the figures include 530 million tons of measured and indicated reserves at Clinton and Inkerman-Balaklava in South Australia.

Relatively small quantities of brown coal are used for purposes other than power generation. In 1962 about 11 million tons was used directly for generation of electric power. More than half of the 4.5 million tons that went into manufacture of lignite briquets was also used in generation of power. The remainder was used for town gas, paper manufacture, and other industries.

Crude Petroleum.—Since the discovery strike at Moonie, Queensland, in December 1961, the Union-Kern-A.O.G. group [10] by the end of 1963 has drilled 17 wells of which all but 2 were potential producers. Developments throughout 1962 and 1963 have brought the field to

[10] Comprising Union Oil Development Corporation, Kern County Land Company, and Australian Oil and Gas Corporation Ltd.

Digitized by Google

production early in 1964. The 15 producers range from 5,817 to 6,918 feet in depth and drill stem tests total 16,561 barrels per day. Three of the wells produce from two zones. The wells have been connected by 3-inch pipe to the fully automated pump station that feeds 191 miles of 10-inch pipeline to carry 7,000- to 10,000-barrels-per-day to refineries at Brisbane. The initial production rate is small by world standards and will furnish less than 5 percent of Australia's crude petroleum requirement.

In retrospect, the discovery of oil in Australia has taken 70 years and expenditure of over A£100 million. The Australian Government assistance has totaled about A£14 million.

The success at Moonie appears to have stimulated nationwide interest in the search for oil and gas. In December 1963 more than 130 companies, syndicates, or individuals held petroleum exploration authorizations to almost 2.7 million square miles. All of Queensland including its offshore areas and most of the land and coastal areas of New South Wales, Victoria, South Australia, and Western Australia have been taken up. At the end of 1962 about 50 geophysical parties were in the field. Well footage drilled in 1962 and 1963 was 150,000 feet more than the total footage of the previous 10 years:

	Feet
1952–61, inclusive	920,775
1962, 70 wells completed	408,511
1963, 128 well completed	662,707

Nearly two-thirds of the 1963 drilling activity—82 holes totaling 405,237—was in Queensland although some drilling was done in all states and territories except Tasmania. Of the 16 wells successfully completed during the year as commercial or potential producers, all were in Queensland, 7 were gas wells and 9 were oil wells.

Petroleum Refinery Products.—Demand for petroluem products has increased at an annual rate of nearly 8 percent in the past decade. To meet this, the refining industry, based on crude petroleum imported mostly from Kuwait, Indonesia, and Saudi Arabia has likewise grown at a rapid rate. Capital investment in marketing and refining facilities was estimated at A£472.7 million to June 1963, an increase of 14.5 percent over the previous year. In 1962 and 1963, domestic refineries supplied nearly 90 percent of the Australian requirement for petroleum products, compared with about 17 percent in 1952. With the added output of the new Amoco Australia Pty, Ltd. and Ampol Petroleum Ltd., refineries near Brisbane, Queensland, and the BP Australia Ltd. refinery at Crib Point near Melbourne, Victoria, domestic production is expected to meet Australian demand for almost all petroleum products.

The Mineral Industry of the Fiji Islands

By J. M. West[1]

THE BRITISH Crown Colony of Fiji produced relatively small quantities of several metals in 1963.

Gold and silver, although less significant than sugar and copra, were important to the economy, contributing about 95 percent of the US$4 million mineral output value in 1963. Other products of minor importance included manganese, iron, and copper ores. Mining and quarrying operations employed about 2,200 persons in 1963.

The Government through its Mines Division and Geological Survey encouraged prospecting and mineral development. The agencies had explored the Sigatoka sand dune area in 1962 outlining an estimated 2 million tons of magnetite in sand. Low-grade lateritic bauxite deposits in the Wainumu Bay-Sarowaqa River district of Vanua Levu were also studied but their potential appeared limited. Bauxite prospecting rights covering more than 100 square miles of the district were held by a subsidiary of Aluminum Co. of Canada Ltd. Banno Bros. of Japan was exploring the Udu mine, a base metal sulfide deposit in the Nukudamu area of Vanua Levu. Reports indicated a sizable copper-zinc orebody had been found.

PRODUCTION

The only mining operation of any size in the islands was the Emperor mine, owned by Emperor Gold Mining Co., Ltd., and located on the edge of a caldera in the Vatukoula goldfield. During 1963 the mine's gold output rose 23 percent and silver rose 20 percent compared with 1962. Elsewhere small tonnages of iron ore were mined in the form of magnetite boulders. A little copper ore was produced from sulfide deposits at Wainivesi, Viti Levu, and manganese ore was mined from diminishing deposits.

Nonmetals:					
Lime	4,750	2,898	3,542	2,592	5,438

TRADE

Gold and silver mill products were shipped to Australia for refining and metal ores to Japan. Mineral imports included petroleum, cement, and steel products. In 1962 about 1 million barrels of petroleum products was imported, largely from Indonesia, Australia, and Singapore. About one-fourth of this was jet fuel. Bunker loadings in 1962 totaled 441,000 barrels including 281,000 barrels of jet fuel. Completion of a new airport at the capital city of Suva and increasing tourist travel was pushing petroleum consumption upward.

COMMODITY REVIEW

Gold and Silver.—During the year Emperor Gold Mining Co., Ltd., continued efforts to operate on a larger scale to overcome a cost-price squeeze. The Government had subsidized mining to the extent of US$5.10 per fine ounce until mid-1961. Mill improvements were made in 1963 which raised gold recovery by several percent. The outlook for reserves was better following new geologic interpretation of the form and extent of mineral deposition. The mine had produced about 2 million ounces of gold and silver through 1963. Eighty percent of the gold value was in telluride-type ore, and the mill used the cyanide process to recover an estimated 91 percent of the gold content of the ore. In 1962 the average mill head was 0.443 ounce gold per ton of ore. A lower average was expected in 1963 as large tonnages of low-grade open-cut ore were being fed to the mill during the year.

The Mineral Industry of New Caledonia

By J. M. West [1]

NICKEL ores and products comprised New Caledonia's most important exports in 1963, amounting to US$44.4 million of a total US$50 million. The country's economy was almost completely dependent on the nickel industry that was dominated by the French company Société Le Nickel. The company operated the mines on the island and a large nickel smelter in the capital city of Noumea. Small quantities of iron ore and chromite also contributed to the country's income. France was the principal trading partner and had the advantage of duty-free exchange of trade goods. Purchases of U.S. mining equipment were below normal in 1963. Mining activities and statistics were reported in the annual statement published by the New Caledonia Service Des Mines.

PRODUCTION

In 1963, output of nickel ore was about one-third higher and production of nickel metallurgical products, matte and ferronickel, nearly 50 percent more than in 1962. Iron ore production remained about the same as in 1962. No chromite mining was reported in1963.

TABLE 1.—Production of metals and minerals

TRADE

Five mineral products, nickel ore, ferronickel (four grades), nickel matte, iron ore, and chromite, were exported in 1963, accounting for over 95 percent of New Caledonia's total value of exports. As in previous years, France was the principal destination of the metallurgical products. Japan as usual purchased nickel ore and for the first time also bought relatively large quantities of nickel matte and ferronickel. Australia and the United States took small tonnages of ferronickel. All iron ore went to Australia, and chromite, shipped from stocks, went mostly to France.

Imports consisted of petroleum products, coal, coke, cement, limestone, and gypsum; most of these going to Noumea and the nickel smelting operations. Total value of mineral products imported in 1963 was about US$6.5 million. About half of the value of mineral imports was in coal and coke from Australia. An estimated 30,000 tons of gypsum was imported from Mexico.

TABLE 2.—Exports of metals and minerals

(Metric tons)

Commodity	1962	1963	Principal destinations, 1963
Chromite	15,009	17,955	Mainly to France.

COMMODITY REVIEW

Iron Ore.—Mines at the extreme southern end of New Caledonia produced iron ore averaging 55.8 percent iron in 1963 for export to the Broken Hill Proprietary Co. Ltd., steelworks in Australia. Extraction, started in 1955–56, was at a consistent level of about 300,000 tons annually.

Nickel and Cobalt.—Nickel ore containing 2.8 to 3.5 percent nickel and about 0.02 percent cobalt on a dry basis was mined by some 15 companies. Over half was mined by the French firm, Société Le Nickel (SLN), which also operated a metallurgical plant at Noumea (Doniambo plant) on the southeast coast. Ore output was higher than in 1962 but fell short of the record set in 1961. Ores came from 15 or

Digitized by Google

more districts, the most important being Thio, on the northeast coast, where SLN operated the Plateau and Bornet group mines. Sizable outputs also came from the Poya, Kouaoua, Ouaco, Tontouta, and Houailou districts. About one-third of the ore mined in 1963 was exported to Japan; the rest went to Noumea for smelting. Exported ores were mainly from the Tomo mines, Tantouta district, and from SLN's Plateau mines.

Maintaining the grade of exports was a special problem, partly due to the 25-percent moisture content of the ore. The refusal point for ore landed in Japan had been 3.0 percent nickel. Because of the clayey ore's moisture pickup in shipment, however, it was necessary to supply a somewhat higher grade, about 3.2 percent nickel. Selective mining to achieve such grade was prematurely depleting reserves. Considering this and generally declining grades in most mines, the Japanese lowered the refusal point to 2.80 percent nickel plus cobalt (dry basis) in their purchase contracts for 1962–63. An f.o.b. price of 50 cents per kilogram (about US$0.23 per pound) of contained nickel plus cobalt was continued for ore assaying 3.20 percent, with differentials applied to higher or lower grades.

SLN's Noumea smelter produced matte containing 77 percent nickel and 23 percent sulfur, and ferronickel in grades ranging 24 to 28 percent nickel. Output was nearly 50 percent higher in 1963 than in 1962 as two new furnaces were fired up. Plant operations had been slowed during 1962 by changes in the matte smelting section involving replacement of four water jacket furnaces with two 20-ton Bessemer converters. An oxygen plant of 150-cubic-meter-per-hour capacity supplied the converters. The company generated its own power with a hydroelectric plant and two thermal plants having capacities of 68,000, 25,000, and 4,000 kilowatts, respectively. Australian coal was imported and converted to coke for smelting. Most nickel matte went to the SLN plant in Havre, France, for reduction to nickel metal. In 1963, however, 4,135 tons of matte was exported to Japan. Most ferronickel also went to France in 1963, except for 1,543 tons exported to Japan, 712 tons to Australia, and 34 tons to the United States. Cobalt was recovered from matte shipped to France.

Others.—A few tons of a magnesian mineral, giobertite, used as a refractory material in nickel smelting was the only other mineral produced in New Caledonia in 1963. Chromite mining stopped at the end of 1962 but shipments continued from stocks, all exported to France. The United States had been a principal buyer of New Caledonian chromite until prices became too high owing to increased mining costs. Tiebaghi, on the northwest coast, was the chief deposit area.

The Mineral Industry of New Zealand

By Lester G. Morrell [1]

THE SMALL mineral industry is basically coal mining and production of construction and chemical nonmetallic minerals. Production of gold and other metallic ores has declined to virtual insignificance, although recent studies of the iron-producing potential of beach sands are encouraging.

The Dominion of New Zealand, comprising the main North and South Islands and adjacent smaller islands, lies about 1,200 miles southeast of Australia. Smallest of the Dominions, its total area of 104,000 square miles is approximately equal to the American State of Colorado. Population, in 1963 was estimated at 2.57 million, including 184,000 native Maoris.

The record NZ£20.3 [2] million value of mineral production in 1963 represents an increase of 10 percent from 1962. The value of New Zealand mineral output has approximately doubled in each decade since 1940. Nonmetals have accounted for more than half of the total value of minerals produced since the early 1950's. The category relationship and total value of minerals produced in selected recent years is as follows:

	Metals	Nonmetals,[1] percent	Fuels	Total value, millions [1]	
Year:					
1950	10.8	22.5	66.7	NZ£9.38	US$26.07
1955	2.3	54.8	42.9	15.85	44.07
1960	2.2	55.2	42.6	19.90	55.33
1961	1.8	56.6	41.6	19.80	55.07
1962	1.5	59.7	38.8	18.44	51.28
1963	1.0	59.4	39.6	20.33	56.53

[1] Exclusive of cement and manufactured fertilizers.

The industrial economy of New Zealand is dominated by agriculture, which accounted for 47 percent of the total NZ£749 million value of New Zealand products, compared with 35 percent for manufacturing and less than 3 percent for mineral industries. In 1963 the minerals industry contributed about 1.4 percent of the gross national product. Employment by mining and quarrying industries in 1963 totaled 7,866 or less than 1 percent of the national labor force, which in that year was estimated at 939,000. Employment during 1961–63 was distributed to the following commodity categories:

	1961	1962	1963
Metals, including gold	157	127	117
Nonmetals	3,791	3,927	3,977
Coal	4,044	3,852	3,660
Petroleum	147	153	112
Total	8,139	8,059	7,866

GOVERNMENT POLICIES AND PROGRAMS

Although the Central Government owns and operates most of the coal production facilities, control of New Zealand mineral industries is predominantly by private owners. For many years the Government has encouraged minerals development and fostered education in minerals sciences. The Mines Department and Geological Survey have rendered technical and research assistance. Financial aid furnished as subsidies, grants, and loans to the mining industry has been more than NZ£70,000 since 1949.

Interest in prospecting and investing in mineral projects is reflected in the record of 293 mineral rights granted in 1963. This included 23 claim grants, 141 prospecting licenses, 64 mineral licenses, 28 water rights, and 37 mining privileges of other types.

Minerals legislation has been related mainly to health and safety and conservation. The early mineral land rights were granted under laws similar to the California formula of claims. More recently, concession systems, particularly to accommodate the needs of petroleum prospecting, have been adopted. Basic laws include the Coal Mines Act of 1925, the Mining Act of 1926, the Petroleum Act of 1937, and the Quarries Act of 1944. Numerous modifications have been added. In 1962 and 1963 amendments provided for controlling mining in national parks and other reserved areas. New regulations were applied to qualifications for coal mine surveyors and for using electricity underground.

The major mineral developments of 1962–63 related to new industrial projects:

An integral part of a vast Australian plan of Commonwealth Aluminium Corp., Pty., Ltd., (COMALCO) was a 1960 agreement with the New Zealand Government. This called for harnessing the hydroelectric energy of Lake Manapouri, near the southern end of South Island, and reducing about 90,000 tons of aluminum annually in a plant to be built at Bluff, 17 miles south of Invercargill.

A comprehensive Government-sponsored development program formulated by the New Zealand Steel Investigating Committee plans to establish an integrated 150,000-metric-tons-per-year steel industry based on electric smelting of titaniferous beach sands by early 1967. The black sand resource found on the west coast of both North and South Islands is believed adequate to supply New Zealand steel needs for more than 50 years.

The country's first petroleum refinery, costing NZ£10 million is scheduled to open in May 1964 at Marsden Point, near Whangarei. It will produce 90 percent of the domestic requirement for petroleum products from imported crude. Initial throughput capacity is expected to be 35 million barrels per year.

SOURCE MATERIAL

Production statistics and progress data have been taken from the mines statement for the year ended December 31, 1963, and previous annual reports of this series. Trade data are from the Statistical Report on the External Trade of New Zealand, compiled and published by the Customs Department, Wellington.

Digitized by Google

PRODUCTION

The high-record value of minerals production in 1963 was achieved largely as a result of economic conditions favorable to the coal-mining industry. Coal output in 1963 was 7.5 percent higher than in 1962 but below the levels of many previous years. Among the 34 mineral commodities produced in 1963, increases were recorded for 20—largest gains being cement, manufactured fertilizers, and silica sand. Production of 11 commodities, including gold and silver, asbestos, structural types of clay, pumice, and coke declined in 1963.

TRADE

Minerals exports from New Zealand were limited to a few thousand ounces of gold to Australia, a small surplus of pumice also to Australia and supplies of semimanufactured and manufactured metal and mineral products to Fiji and other Pacific Islands.

Digitized by Google

Imported mineral fuels and processed or manufactured mineral products comprise about one-third of the nation's total imports as indicated by the following values of mineral product categories for the 1960–63 period.

Category:	Value in millions			
	1960	1961	1962	1963
Mineral fuels	NZ£ 20.7	NZ£ 21.6	NZ£ 22.1	NZ£ 23.2
Chemicals and fertilizers	20.3	22.7	22.2	26.6
Metals and manufactures thereof	39.3	46.4	40.0	44.3
All other	172.9	197.6	160.1	202.2
Total imports	253.2	288.3	244.4	296.3

Nearly all of the mineral-product imports originated in Australia and the United Kingdom. Principal destination and source countries by commodities are indicated in the accompanying trade tables.

TABLE 2.—Exports of metals and minerals

COMMODITY REVIEW

METALS

Copper Ore.—The 30 or more known occurrences of copper ore in New Zealand are considered uneconomic. Nevertheless more than 6,000 metric tons of copper ores have been produced in past mining efforts. In the early 1950's about 1,200 tons of copper sulfide ore was shipped to Australia from the Pakotai Copper mine in North Auckland. In 1962 and 1963, oxide and carbonate copper ores from near Parakao, also in North Auckland, were surface mined and used locally as a fertilizer additive.

Gold.—From 1860 through 1963, gold production amounted to more than 28 million troy ounces. However, with exhaustion of reserves, output has steadily declined from the 1906 peak of 5.5 million ounces to less than 15,000 ounces in 1963. For the 3 years 1959–61, gold production by types of mining was as follows:

	Quantity troy ounces		
	1959	*1960*	*1961*
Vein mining	953	342	336
Alluvial workings	700	486	501
Dredges	35,105	32,498	27,457
Total	36,758	33,326	28,294

Most 1963 production came from the Kanieri Gold Dredging, Ltd., operation on the Taramakay River near Kumara in Westland, South Island. Dredging 4.2 million cubic yards yielded 12,477 ounces. The Clutha dredge on the Earnscleugh Flats, near Alexandra recovered 1,226 ounces from 85,000 cubic yards before this operation was suspended in March 1963. The Kanieri dredge was the only commercial-scale gold operation in New Zealand at the yearend. Private individuals, employed part time, accounted in 1963 for about 500 ounces from small-scale sluicing operations.

Iron Ore.—A small quantity of limonite iron ore is produced each year to supply the needs of this type material in gas purification, stock licks, and manufacturing bricks and cement. The sources are small deposits in North Auckland and one larger deposit at Onekaka, near Nelson, on the South Island. The Onekaka deposit was mined intermittently to feed a small blast furnace between 1922 and 1935. Reserves reportedly consist of about 9.5 million tons, ranging from 35 to 49 percent Fe content.

The accumulation of iron-rich beach sands on the west coast of both the North and the South Islands is the subject of extensive Government investigation. The Government-established New Zealand Steel Investigating Co. in March 1961 designated Battelle Memorial Institute (United States) to conduct the investigation. Recommendations made public early in 1963 [3] called for establishment of an iron and steel industry in the South Auckland area. The initial plant was to be completed late in 1966, having an annual capacity of about 150,000 tons with provision for expansion by 1973 to 270,000 tons. The resource base for the plan was a 1955 estimate by J. Luke of the New Zealand Geological Survey [4] totaling nearly 800 million tons of titanomagnetite and ilmenite type ores. The New Zealand Steel Investigating Co., Ltd., recommended reservation of the major iron-sands deposits by legislation.

Silver.—Most of the silver produced in past years in New Zealand has been a byproduct of gold from the vein mines of the Hauraki field near Thames, North Auckland. The recent meager output of silver has been contained in gold recovered by the gold-dredging operations.

Tungsten Ore.—The Glenorchy field, on Lake Wakatipu, South Island, has been the source of all scheelite ore produced in recent years. Fewer than a dozen miners were employed mining tungsten ore in 1962 and 1963. The ores are treated locally in a small State-owned mill; concentrates are exported, usually to the United Kingdom.

NONMETALS

Asbestos.—Until the operation was closed in December 1963, the only important domestic source of chrysotile asbestos was the Hume Industries (N.Z.) Ltd., quarry and works in the Upper Takaka Valley, on the northwestern peninsula of South Island. The fiber which occurs in serpentine is relatively short, is mined by opencut, and is milled on the site. The bulk of the output, amounting to a few hundred tons annually, has been used locally in manufacturing wallboard and asbestos cement products. The domestic production supplies but a small part (approximately 10 percent) of the total requirement for crude asbestos. The principal sources of imports are the Republic of South Africa and Canada.

Bentonite.—Most of the bentonite production has been from deposits worked by New Zealand Bentonite (Porangahau), Ltd., at Porangahau, about 60 miles south of Napier, on the North Island. In 1962

and 1963 bentonite of a nonswelling type that could be beneficiated was being investigated in the Hororata-Coalgate area, 40 miles east of Christchurch.

Clays.—The clay-products industry, based on domestic clay deposits, according to 1960–61 data comprises 51 establishments with 1,800 employees. The industry is organized into two trade groups: New Zealand Heavy Clay Product Manufacturers Association, and New Zealand Pottery & Ceramic Manufacturers Association. Quarries and plants are widely scattered throughout both islands. The majority of these facilities produce structural clay products, such as building bricks, tile pipes, roofing tiles, and firebrick. The seven pottery-clay plants produce insulators, crockery, artware, and sanitary ware.

Cement.—Since 1956, the number of cement producers in New Zealand has doubled and demonstrated annual production capacity has increased from 451,000 metric tons to more than 720,000 tons. This expansion has not only met the needs of the recent high level of industrial growth but has virtually eliminated the need for imports. Less than 3,000 tons, mostly special type cements, were imported in 1963, compared with 175,000 yearly in the 1952–57 period. Production of locally quarried limestone, marl, and sand ingredients for cement has approximately paced the growing output of cement. The necessary supply of gypsum is not found in New Zealand and must be imported. Imports of 80,000 to 90,000 tons of crude gypsum in 1962 and 1963 came from Australian quarries. About half would be used in cement. According to 1960–61 data, the 6 cement plants employed 793 workers. Raw materials consumed in that fiscal period included 542,000 tons limestone; 613,000 tons clay, marl, and cement rock; and 26,000 tons of gypsum.

The New Zealand cement industry includes the following producers:

Golden Bay Cement Co., Ltd., Tarakohe, near Nelson, West Coast District, which produced 149,000 tons in 1963.

Milburn Lime & Cement Co., Ltd., having quarries at Makareao, Milburn, and Burnside, near Dunedin, Southern District.

New Zealand Cement Co., Ltd., Cape Foulwind, Westport, West Coast District, which produced 72,000 tons in 1963.

Southland Cement Co., Ltd., Clifden, 40 miles northwest of Invercargill, Southern District.

Waitomo Portland Cement Co., Ltd., limestone quarried by Beros Bros., Ltd., Tekuiti, South Auckland District.

Wilson (N.Z.) Portland Cement Co., Ltd., Quarries at Portland and Waro, near Whangarei, North Auckland District.

Diatomite.—Production of diatomite has fallen steadily from more than 7,000 tons annually in 1958–59 to less than 1,630 tons in 1963. The previous production was mostly from two deposits operated by J. Mathis and W. J. Strevens, respectively, at Hunua and Papakura near Auckland. The diatomite from these workings was used in manufacture of light concrete. Since 1961 the principal supplier has been Pozzolan Products, Ltd., near Rotorua. Small quantities have also been reported from quarries at Ngakuru and Foulden Hill, near Middlemarch, on the South Island.

Pumice.—Production of pumice in 1963 was approximately half the average output recorded in the previous 4 years. According to 1958

Digitized by Google

data, principal producers were Gilberd & Son, Ltd., at Wanganui, 100 miles north of Wellington and the New Zealand Pumice Co., Ltd., at Horotiu near Hamilton. Smaller production was reported by Warnock Bros. at Horotiu and by A. F. Nicholson at Aramoho at Wanganui. Pumice is the principal nonmetallic mineral export of New Zealand.

Salt.—Since 1952, salt has been produced by solar evaporation of sea water by the Dominion Salt Co., Ltd., at Lake Grassmere, on the easternmost point of South Island. Production is subject to weather conditions and therefore varies widely from year to year. This source normally supplies from one-fourth to one-half of the national salt requirement. The remainder of the supply is imported from United Kingdom and Australia.

Silica Sand.—According to 1960–61 data, 56 establishments employing 1,320 persons comprised the New Zealand glass and glass products industry. The mineral resource base of this industry is high-grade silica sand quarried at Parengarenga on the northern tip of North Island and at Mount Somers, near Christchurch on the east coast of South Island. At Parengarenga, three companies—N.Z. Glass Manufacturing Co., Ltd.; Gulf Freighters, Ltd.; and Parry Bros. Ltd., produced 52,200 tons in 1962. At Mount Somers; Crown Crystal Glass Pty., Ltd.; Newburn Coal and Minerals, Ltd., and two smaller producers accounted in 1962 for 11,100 tons.

MINERAL FUELS

Coal.—For many years, coal has been the most valuable domestic mineral product. Before 1954 its importance outweighed all other mineral products. In 1963 the value of coal produced accounted for two-fifths of the total. The Dominion Government owns and operates 90 of the 142 mines that reported production in 1963. Eight mines are controlled jointly by Government and private interests, and 44 are owned by private individuals and companies. In 1963, 55 percent of the production was from State-owned mines. Although there has been some migration of activity among coalfields, national output since 1950 has been quite steady, varying only between 2.5 and 3.1 million metric tons per year. The trend has been up in recent years; the peak was recorded in 1960. Geographically, the coalfields of New Zealand are widely distributed. The bulk of the national output consists of subbituminous-rank coal from the Waikato and Taranaki fields in the west-center of North Island. Most of the bituminous, including coking varieties, is found in Buller and Keefton coalfields near Greymouth and Westport on the northern end of South Island. A few hundred tons of anthracite are reported each year from a mine at Lake Coleridge, west of Christchurch. The lignite occurrences are widely scattered in the southern half of South Island. Quantities of coal produced in 1962 and 1963, compared with 1950, from each of the principal coalfields were:

Digitized by Google

Coalfield:	Quantity, thousand metric tons		
	1950	1962	1963
North Auckland	55	3	3
Waikato and Taranaki	940	1,257	1,426
Nelson	8	18	18
Buller	481	287	262
Reefton	111	107	110
Grey	519	423	405
Canterbury	30	19	18
Otago	177	122	135
Southland	391	355	409
Total	2,712	2,591	2,786

In 1959 the New Zealand Mines Department and Geological Survey compiled national reserve data, using classifications accepted by the U.S. Bureau of Mines and the Commonwealth Mineral Resources Survey.[5] These data are summarized in the following table:

Rank:	Reserve, thousand metric tons		
	Measured	Indicated	Inferred
Bituminous	41,540	38,060	52,100
Subbituminous	63,230	156,180	309,700
Lignite	15,950	43,790	405,200
Total	120,720	238,030	767,000

The long-term trend of coal production statistics has recorded a growing proportion of output from strip (opencast) mines, a decline in the total employees, and an increase in the output per man. These developments are indicated in the 5-year annual intervals compared with 1963 data as follows:

	1945	1950	1955	1960	1963
Strip mines:					
Output thousand tons	460	724	780	1,138	1,138
Employees	332	439	342	467	364
Tons per man-year	1,384	1,649	2,279	2,436	3,126
Underground mines:					
Output thousand tons	2,419	1,988	1,818	1,922	1,648
Employees	5,260	5,149	4,187	3,834	3,296
Tons per man-year	459	386	434	501	500
Total all mines:					
Output thousand tons	2,879	2,712	2,598	3,060	2,786
Employees	5,592	5,588	4,529	4,301	3,660
Tons per man-year	515	486	573	711	761

According to 1961 figures, the manufacturing industries accounted for one-third of the total domestic consumption of coal. Percentage distribution to principal consumers was as follows: Electric power generation, 21.0; household, 18.7; dairy establishments, 10.0; gasworks, 9.7; railroads, 7.5; cement works, 6.0; meat establishments, 5.3; pulp and paper mills, 4.4; miscellaneous manufacturing, 7.5; and all others, 9.9.

Coke and Briquets.—The public utility companies that supply gas to the cities of Auckland, Wellington, and Christchurch, as well as sev-

[5] Mines Department. Mines Statement, for the Year Ended December 31, 1959. Gov't. Printer, Wellington, New Zealand, 1960, p. 154.

Digitized by Google

eral smaller towns, are the source of the low-temperature coke produced in New Zealand. Hard, or high-temperature coke is produced only by Smokeless Fuel Co., Ltd., of Sockburn.

Coal briquets, locally termed carbonettes, are manufactured by Waikato Carbonisation, Ltd., at Rotowaro.

Petroleum.—Occurrences of petroleum are known in North Auckland, in various parts of Taranaki County, and over wide areas along the east coast of North Island, as well as in several South Island areas, notably the vicinity of the coal measures near Greymouth. The only appreciable commercial production has been from the wells of Egmont Oil Wells, Ltd., at Moturoa, near New Plymouth, on North Island. Annual production of 4,000 barrels of crude petroleum and 4 to 5 million cubic feet of natural gas has been recorded from the 4 test wells of the company. Production potential of this field, for an expected life of 25 to 30 years, has been estimated at 60 million cubic feet of natural gas per day, from which 4,500 barrels of oil and 35 million cubic feet of treated gas can be separated. Pipelines to carry oil to the shipping port at New Plymouth, and gas to the consuming centers on the North Island are being planned.

Activity in the search for petroleum throughout New Zealand continued at a high level during 1963. More than 300 petroleum prospecting licenses were in force, covering a total of 51,340 square miles. Four-fifths of the land area of North Island and one-fourth of South Island were held under concession to 25 individuals and companies.

The first oil refinery in New Zealand, at Marsden Point, adjacent to Whangarei Harbor, is scheduled to come on-stream early in 1964. The refinery has been designed to meet the requirements of New Zealand for petroleum products until 1967 when further expansion will be considered. Initial annual production capacity is for 1,170,000 metric tons of gasoline, 498,000 tons of diesel oil, 528,000 tons of fuel oil, and 122,000 tons of bitumen. Feedstock for the refinery will come from countries of the Middle East and South East Asia. Eventually indigenous oil such as the condensate or crude from New Plymouth will also be processed at Marsden Point.
